### Brief Summary of Findings on the Association Between Asthma and Severe COVID-19 Outcomes

Overall, 69 studies were retrieved that reported adjusted measures of effect on the association between underlying asthma and severe COVID-19 outcomes including mortality, intensive care unit (ICU) admission, intubation, ventilation, hospitalization, and readmission. All studies were rated as having a moderate to low threat to internal validity except for one study (Gottlieb 2020).

- <u>Asthma</u>: Data indicate underlying asthma is associated with an increase in ICU admission<sup>1-19</sup> (N =836,857) and hospitalization<sup>2,5,7,8,12,14,17,20-35</sup> (N = 861,886) among COVID-19 patients. Data suggest underlying asthma is associated with an increase in ventilation<sup>1,7,34</sup> (N = 5,403) and indicate it is associated with readmission<sup>36,37</sup> (N = 8,990). Data were inconsistent and inconclusive on the associations between underlying asthma and mortality<sup>1-12,18,31,33-35,38-61</sup> (N = 4,889,078) and intubation<sup>10,12-14,16,48</sup> (N = 223,519) among COVID-19 patients.
- <u>Severity</u>: Data from six studies<sup>2,22,34,41,45,62,63</sup> (N = 89,578) suggest severe asthma is associated with an increase in hospitalization when compared to less severe asthma. Data are inconsistent and inconclusive on the association between severity of underlying asthma and the outcomes of mortality,<sup>2,9,34,45,63-66</sup> ICU admission,<sup>2,9,45</sup> and ventilation;<sup>34,45</sup> however, heterogeneous measures of severity were used across studies. Several studies<sup>2,34,39,45,63,64</sup> report COVID-19 patients with no asthma as a comparison group and did not report data stratified by severity for asthma-specific populations.
- <u>Treatment</u>: Data from five studies<sup>39,41,45,50,67</sup> are inconclusive on the association between asthma treatment and the outcomes of mortality, ICU admission, ventilation, and hospitalization among COVID-19 patients with underlying asthma. These studies use different combinations of steroids and other asthma medications as exposure measures. Several studies<sup>39,45,50</sup> did not report data stratified by medication type for asthma-specific populations and instead report COVID-19 patients with no asthma as a comparison group.
- <u>Comorbidities</u>: Data from two studies<sup>41,67</sup> (N = 12,800) suggest an increased risk of mortality for COVID-19 patients with asthma and chronic heart disease when compared with COVID-19 patients with asthma alone. Data are inconsistent and inconclusive for other comorbidities including diabetes, hypertension, obesity, and chronic kidney disease. Data from one study<sup>33</sup> (N = 15,690) suggest there is no association between obesity and hospitalization among COVID-19 patients with asthma.
- <u>Risk Markers</u>: Data from eight studies<sup>30,31,33,41,45,67-69</sup> (N = 145,330) suggest female sex is associated with an increase in hospitalization among COVID-19 patients with underlying asthma. Data are inconclusive and inconsistent for age, race, ethnicity, and smoking status. Several studies report COVID-19 patients with no asthma as a comparison group and did not stratify severity data for asthma-specific populations.

### A. Methods

The aim of this review is to identify and synthesize the best available evidence to answer the question: "what is the association between asthma and severe COVID-19?" This evidence will be used to update the Centers for Disease Control and Prevention (CDC) website on underlying conditions and enable the creation of a provider-specific website with more rigorous information.

The methods for underlying conditions and risk factors are outlined in the webpage, <a href="https://www.cdc.gov/coronavirus/2019-ncov/science/science-briefs/systematic-review-process.html">https://www.cdc.gov/coronavirus/2019-ncov/science/science-briefs/systematic-review-process.html</a>. These methods were established in May 2021 and are used for conditions and risk factors where CDC conducted the review.

Below are methodologic highlights and additional methods unique to this review. For more information, please visit <a href="https://www.cdc.gov/coronavirus/2019-ncov/science/science-briefs/systematic-review-process.html">https://www.cdc.gov/coronavirus/2019-ncov/science/science-briefs/systematic-review-process.html</a>.

#### A.1. Literature Search

A list of search terms was developed to identify the literature most relevant to the population, exposure, comparator, and outcome (PECO) question. Clinical experts and library scientists were consulted to develop a robust list of search terms. These terms were then incorporated into search strategies, and these searches were performed in OVID using the COVID-19 filter from the end of the previous literature search (December 2020). The detailed search strategies for identifying primary literature and the search results are provided in the Appendix. Subject matter experts supplemented the literature search results by recommending relevant references published before December 2020. References were included if retrieved by the chronic lung disease literature search and reported exposures and outcomes relevant to this review.

### A.2. Study Selection

Titles and abstracts from references were screened by dual review (M.C., A.H., J.H., J.K.K., M.M., C.O., D.O.S., K.T.R., T.R., C.N.S., E.C.S., or M.W.).

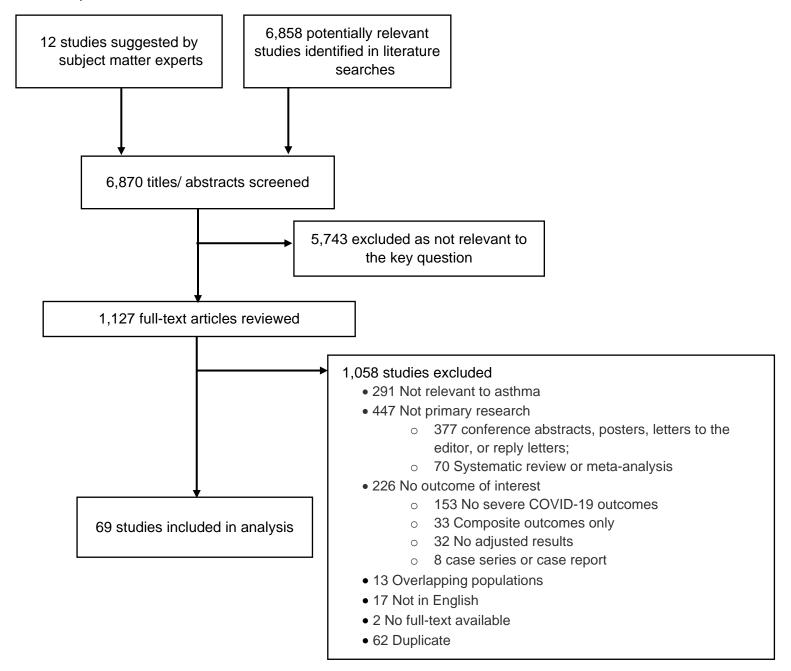

Full-text articles were retrieved if they were:

- 1. Relevant to the PECO question;
- 2. Primary research, and
- 3. Written in English.

Part B presents the full list of exclusion criteria. The full texts of selected articles were then screened by two independent reviewers, and disagreements were resolved by discussion (M.C., J.H., J.K.K., C.O., D.O.S., T.R., C.N.S., E.C.S., or M.W.).

After the full-text screening was complete, a bibliography of the articles selected for inclusion was vetted with subject matter experts. Additional studies suggested by the subject matter experts were screened for inclusion as described above. The results of the study selection process are depicted in Figure 1.

Figure 1. Results of the Study Selection Process

## A.3. Data Extraction and Synthesis

Methodologic data and results of relevant outcomes from the studies meeting inclusion criteria were extracted into standardized evidence tables. Data and analyses were extracted as presented in the studies. For the purposes of this review:

- Confidence intervals were determined for each outcome; width of the CI was defined as "wide" if it was within the upper tertile of the range of confidence interval widths.
- Any determination of association based on measures of association was made based on the following rules of thumb:
  - Measures of association greater than 1.1 were determined as "suggestive" or "indicative" of an increase in risk, regardless of confidence interval or statistical significance.
  - Measures of association between 0.9 and 1.1 were determined to be "suggestive" or "indicative" of no difference, and confidence intervals must have crossed the null
  - Measures of association less than 0.9 were determined to be "suggestive" or "indicative" of a decrease in risk, regardless of confidence interval or statistical significance
  - If the overall direction of evidence was consistent, a Bayesian approach was taken to aggregating the evidence and determining the strength of association.
- Statistical significance was defined as  $p \le 0.05$ .
- Studies with denominators smaller than 10% of the median denominator for this review (N = 7,137) were considered to have a small sample size (N < 714).

# A.4. Internal Validity Assessment

The internal validity associated with each study was assessed using scales developed by the Division of Healthcare Quality Promotion and scores were recorded in the evidence tables. Part B includes the questions used to assess the quality of each study design. The strength, magnitude, precision, consistency, and applicability of results were assessed for all comparators. The overall confidence in the evidence base is reported in the aggregation tables in Part B.

### A.5. Reviewing and Finalizing the Systematic Review

Draft findings, aggregation tables, and evidence tables, were presented to CDC subject matter experts for review and input. Following further revisions, the summary will be published on the CDC website.

### **B.2. Study Inclusion and Exclusion Criteria**

**Inclusion Criteria:** Studies were included at the title and abstract screen if they:

- were relevant to the key question "what is the association between chronic lung disease and severe COVID-19?";
  - Studies deemed not relevant included those that reported autopsy results, and examined lung transplant, cancer, or immunocompromised populations;
- were primary research;
- were written in English (can be seen as [language] in title); and
- examined humans only.

**Exclusion Criteria:** Studies were excluded at full text review if they:

- did not answer the key question "what is the association between asthma and severe COVID-19?";
- were not available as full-text;
- were not available in English;
- were not primary research articles that underwent the peer-review process including
  - conference abstracts, posters, letters to the editor, or reply letters;
  - systematic reviews, narrative reviews, or meta-analyses,
- reported only composite outcome measures for "severe COVID-19";
- did not report adjusted results; and
- reported data from the same population as examined in another study (in these cases, the study with the larger study population or longer study period was maintained in the analysis).

# **B.3. Evidence Review: Asthma and Severe COVID-19**

# **B.3.a. Strength & Direction of Evidence**

### Table 2. The Association between Asthma and Severe COVID-19 Outcomes

| Outcome   | Results   |
|-----------|---|
| Mortality | <ul> <li>Evidence is inconsistent and inconclusive on the association between underlying asthma and mortality among COVID-19 patients.</li> <li>Strength of Association: Thirty-eight studies<sup>1-12,18,31,33-35,38-43,46-50,52-61</sup> report adjusted measures of association ranging from 0.12 (95% CI: 0.01-1.14) to 4.58 (95% CI: 2.58-8.13) .</li> <li>Precision of Association: Of the 36 studies reporting confidence intervals, 15<sup>1,3,6,7,9,18,38,39,41,47-49,52,54,56</sup> are wide and 25<sup>2,3,6-11,18,31,33,35,38,41-43,46,48,49,52,55-57,60,61</sup> include the null.</li> <li>Consistency of Association: Results are inconsistent.</li> </ul> |

• Applicability of Association: Settings and populations are applicable.

Forty studies  $^{1-12,18,31,33-35,38-44,46-61}$  (N = 4,889,078) report data on underlying asthma and mortality among COVID-19 patients. Two studies  $^{5,49}$  have a low threat to internal validity and  $38^{1-4,6-12,18,31,33-35,38-44,46-48,50-61}$  have a moderate threat to internal validity.

- Twelve studies<sup>1,9,38,39,41,44,47,48,51,52,54,60</sup> (N = 2,066,387) suggest that underlying asthma is associated with an increase in mortality among COVID-19 patients. Nine cohort studies<sup>1,9,38,39,41,47,48,54,60</sup> (N = 97,648) report adjusted effect measures ranging from 1.14 (95% CI: 0.98-1.32) to 4.58 (95% CI: 2.58-8.14). One modeling study<sup>52</sup> (N = NR) reports an association between US county-level COVID-19 case fatality rates and county-level, age-adjusted mortality due to asthma among counties with high COVID-19 mortality surrounded by other counties with high COVID-19 mortalities. This study reports a protective association for counties with low COVID-19 mortality surrounded by other counties with low COVID-19 mortalities. Two ecological studies<sup>44,51</sup> (N = 1,968,739) suggest an association between underlying asthma and an increase in mortality. One<sup>44</sup> (N = NR) reports that COVID-19 fatality is positively related to asthma prevalence and the other<sup>51</sup> (N = 1,968,739) reports that COVID-19 lag-adjusted case fatality rates increase as asthma prevalence increases in US counties.
  - Of these studies, nine<sup>1,9,38,39,41,47,48,52,54</sup> have wide confidence intervals and five<sup>9,38,41,48,60</sup> cross the null, decreasing confidence in these findings. One study<sup>54</sup> has a small sample size, two studies<sup>47,48</sup> report a low number of deaths, and three studies<sup>9,38,47</sup> report a low prevalence of asthma in the study population, one<sup>39</sup> of which compares severe asthma to no asthma.
- Twelve studies<sup>2,3,8,11,33,42,46,49,53,55,57,61</sup> (N = 911,127) report no association between mortality and underlying asthma among COVID-19 patients. Eleven cohort studies<sup>2,3,8,11,33,42,49,53,55,57,61</sup> (N = 910,075) report adjusted effect measures ranging from 0.95 (95% CI: 0.83-1.08) to 1.1 (95% CI: 0.6-2.04) and all confidence intervals include the null. One ecological study<sup>46</sup> (N=1,052 counties) reports no association between the prevalence of underlying asthma and COVID-19 case fatality risk.
  - Of these studies, two<sup>3,49</sup> have wide confidence intervals, decreasing confidence in the findings. Two studies<sup>49,57</sup> report a low prevalence of underlying asthma among the study population, one<sup>49</sup> of which defines asthma as moderate to severe asthma, and one study<sup>53</sup> has a small sample size.
- Sixteen studies<sup>4-7,10,12,18,31,34,35,40,43,50,56,58,59</sup> (N = 1,907,498) suggest that underlying asthma is associated with a decrease in mortality among COVID-19 patients. Fourteen cohort studies<sup>4,6,7,10,12,18,31,34,35,40,43,50,56,58</sup> (N = 1,398,985), one case-control study<sup>5</sup> (N=502,656), and one cross-sectional study<sup>59</sup> (N = 5,857) report effect measures ranging from 0.12 (95% CI: 0.01-1.14) to 0.88 (95% CI: 0.69-1.1).
  - Of these studies, three<sup>6,7,18</sup> have wide confidence intervals and eight confidence intervals<sup>6,7,10,18,31,35,43,56</sup> include the null, decreasing confidence in these findings. Four studies<sup>6,7,54,56</sup> have a small sample size and five<sup>6,10,34,50,56</sup> report a low number of deaths. Two studies<sup>10,58</sup> report a low prevalence of underlying asthma.

#### **ICU** admission

Evidence indicates an increase in ICU admissions among COVID-19 patients with underlying asthma.

• Strength of Association: Nineteen studies<sup>1-19</sup> report adjusted measures of association ranging from 0.51 (95% CI: 0.41-0.64) to 2.5 (95% CI: 1.2-5.2).

- Precision of Association: Of the 18 studies reporting confidence intervals, seven<sup>1,6,8,13,17-19</sup> are wide and nine<sup>2,3,6,7,9,11,13,17,18</sup> include the null.
- Consistency of Association: Results are consistent.
- Applicability of Association: Settings and populations were applicable.

Nineteen studies<sup>1-19</sup> (N =836,857) report data on underlying asthma and ICU admission among COVID-19 patients. One study<sup>5</sup> has a low threat to internal validity and 18<sup>1-4,6-19,45</sup> have a moderate threat.

- Twelve studies<sup>1,3-6,8,10,13,16-19</sup> (N = 719,215) suggest that underlying asthma is associated with an increase in ICU admissions among COVID-19 patients. Eleven cohort studies<sup>1,3,4,6,8,10,13,16-19</sup> (N = 216,559) and one case-control study<sup>5</sup> (N = 502,656) report effect measures ranging from 1.17 (95% CI: 0.4-2.41) to 2.5 (95% CI: 1.2-5.2).
  - Of these studies, seven<sup>1,6,8,13,17-19</sup> have wide confidence intervals and five<sup>3,6,13,17,18</sup> include the null, decreasing confidence in the findings. Two studies<sup>6,17</sup> report a low number of ICU admissions and three<sup>6,13,18</sup> have small sample sizes. One study<sup>10</sup> reports a low prevalence of underlying asthma in the study population.
- Three cohort studies<sup>2,11,14</sup> (N = 160,121) report no association between ICU admission and underlying asthma among COVID-19 patients.
  - One study<sup>2</sup> (N = NR) reported an effect measure suggesting no association between underlying asthma and ICU admission among COVID-19 patients when adjusting for all other respiratory disease, ethnicity, socioeconomic status, region of England, BMI, smoking status, non-smoking-related illness and smoking related illness [aHR 1.08 (95% CI: 0.93-1.25), p = NR].
  - One study<sup>11</sup> (N = 5,104) reported an effect measure suggesting no association between underlying asthma and ICU admission among COVID-19 patients when adjusting for age, sex, education level, and a combined covariate for cardiac disease [aHR 1.07 (95% CI: 0.65-1.75), p = 0.79].
  - One study<sup>14</sup> (N = 155,017) reported an effect measure suggesting no association between underlying asthma and ICU admission among COVID-19 patients when adjusting for sociodemographic and clinical characteristics [aRR 0.98 (95% CI: NR), p > 0.05]. The study did not report a confidence interval and reported a low prevalence of underlying asthma in the study population, decreasing confidence in the findings.
- Four studies<sup>7,9,12,15</sup> (N = 18,859) report data that suggest underlying asthma is associated with a decrease in ICU admissions among COVID-19 patients and reported adjusted effect measures ranging from 0.51 (95% CI: 0.41-0.64) to 0.66 (95% CI: 0.30-1.46).
  - o Of these studies, two<sup>7,9</sup> have confidence intervals that include the null, decreasing confidence in the findings. Two studies<sup>7,15</sup> have a small sample size and the other<sup>9</sup> reports a low prevalence of underlying asthma.

#### Intubation

The evidence is inconsistent and inconclusive on the association between underlying asthma and intubation among COVID-19 patients.

- Strength of Association: Six studies<sup>10,12-14,16,48</sup> report adjusted measures of association ranging from 0.56 (95% CI: 0.17-1.86) to 1.77 (95% CI: 0.99-3.04).
- Precision of Association: Two studies<sup>12,13</sup> report wide confidence intervals and four<sup>10,12,13,48</sup> include the null.
- Consistency of Association: Results are inconsistent.
- Applicability of Association: Settings and populations are applicable.

Six studies  $^{10,12-14,16,48}$  (N = 223,519) report data on underlying asthma and intubation among COVID-19 patients and all have a moderate threat to internal validity.

- Three cohort studies<sup>13,16,48</sup> (N = 18,559) report effect measures suggesting that underlying asthma is associated with an increase in intubation among COVID-19 patients.
  - One study<sup>13</sup> (N = 502) reports an effect measure suggesting underlying asthma is associated with an increase in intubation among COVID-19 patients when adjusting for age, gender, and obesity [aOR 1.77 (95% CI: 0.99-3.04), p = 0.06]. The study has a small sample size and the confidence interval is wide and includes the null, decreasing confidence in the finding.
  - One study<sup>48</sup> (N = 935) reports an effect measure suggesting underlying asthma is associated with an increase in intubation among COVID-19 patients when adjusting for demographic variables and BMI [aOR 1.18 (95% CI: 0.45-1.32), p = 0.35]. The confidence interval includes the null, decreasing confidence in the finding.
  - One study<sup>16</sup> (N = 17,122) report an effect measure indicating underlying asthma is associated with an increase in intubation among COVID-19 patients. The association remains when adjusting for age, gender, degree of dependency, dyslipidemia, chronic heart failure, severe chronic renal failure, cancer, COPD, respiratory rate >20, and risk category [aOR 1.24 (95% CI: 1.01-1.55), p = 0.049].
- Three cohort studies<sup>10,12,14</sup> (N = 204,960) report adjusted effect measures suggesting that underlying asthma is associated with a decrease in intubation among COVID-19 patients.
  - One study<sup>10</sup> (N = 39,420) reports an effect measure suggesting that underlying asthma is associated with a decrease in intubation among COVID-19 patients. The association remains when adjusting for age, sex, and other systemic comorbidities [aOR 0.61 (95% CI: 0.29-1.3), p = 0.2]. The confidence interval includes the null, and the prevalence of underlying asthma in the study population is low, decreasing confidence in the finding.
  - One study<sup>12</sup> (N = 10,523) reported an effect measure suggesting that underlying asthma is associated with a decrease in intubation among COVID-19 patients. The association remained when adjusting for COVID-19 disease severity, comorbidities, and concurrent therapies [aOR 0.56 (95% CI: 0.17-1.86), p = 0.35]. The confidence interval was wide and included the null, decreasing confidence in the finding.
  - One study<sup>14</sup> (N = NR) reports an effect measure indicating that underlying asthma is associated with a decrease in intubation among COVID-19 patients when adjusting for sociodemographic characteristics, medical history, and the interaction of age and cardio-metabolic comorbidities [aRR 0.77 (95% CI: NR), p<0.01]. The study does not report a</li>

|                 | confidence interval and reports a low prevalence of underlying asthma in the study population, decreasing confidence in the finding.   |
|-----------------|--|
| Ventilation     | <ul> <li>The evidence suggests an increase in ventilation among COVID-19 patients with underlying asthma.</li> <li>Strength of Association: Three studies<sup>1,7,34</sup> report adjusted measures of association ranging from 0.69 (95% CI: 0.36-1.29) to 2.1 (95% CI: 1.3-3.5).</li> <li>Precision of Association: Two studies<sup>1,7</sup> report wide confidence intervals and two<sup>7,34</sup> include the null.</li> <li>Consistency of Association: Results are inconsistent.</li> </ul>  |

The study has a small sample size and a wide confidence interval that includs the null, decreasing</li> </ul> |
|                 | <ul> <li>One cohort study<sup>34</sup> (N = 3,248) suggests that underlying asthma is associated with a decrease in ventilation among COVID-19 patients.</li> <li>One study<sup>34</sup> (N = 3,248) reports an effect measure suggesting underlying asthma is associated with a decrease in mechanical ventilation when adjusting for age, sex, race, ethnicity, payor, smoking status, BMI, and Charlson comorbidity index [aHR 0.69 (95% CI: 0.36-1.29), p = NR]. The confidence interval includes the null and the study reports a low number of ventilations, decreasing confidence in the results.</li> </ul>  |
| Hospitalization | Evidence indicates an increase in hospitalization among COVID-19 patients with underlying asthma.  • Strength of Association: Twenty-three studies <sup>2,5,7,8,12,14,17,20-35</sup> report adjusted measures of association ranging from 0.28 (95% CI: 0.14-0.55) to 4.53 (95% CI: 1.39-14.79).   |

- Precision of Association: Nine studies<sup>7,17,20,24,27,28,31,32,35</sup> report wide confidence intervals and eight<sup>7,17,22,25,26,31,34,35</sup> include the null.
- Consistency of Association: Results are consistent.
- Applicability of Association: Settings and populations are applicable.

Twenty-three studies  $^{2,5,7,8,12,14,17,20-35}$  (N = 861,886) report data on underlying asthma and hospitalization among COVID-19 patients. One study has a low threat to internal validity,  $21^{2,7,8,12,14,17,20-25,27-35}$  a moderate threat, and one high threat to internal validity

- Sixteen studies<sup>2,5,8,17,20-22,24,27-33,35</sup> (N = 682,894) suggest that underlying asthma is associated with an increase in hospitalization among COVID-19 patients. Thirteen cohort studies<sup>2,8,17,20-22,27-29,31-33,35</sup> (N = 135,521) and two case-controls<sup>5,24</sup> (N = 503,908), and one cross-sectional<sup>30</sup> (N = 43,465) report effect measures ranging from 1.11 (95% CI: 1.02-1.2) to 4.53 (95% CI: 1.39-14.79). One cohort study<sup>45</sup> reported an increase in hospitalization among COVID-19 patients with active asthma, however there was no association for COVID-19 patients with inactive asthma.
  - Of these studies, eight<sup>17,20,24,27,28,31,32,35</sup> have wide confidence intervals and four<sup>17,22,31,35</sup> include the null, decreasing confidence in the findings. Two studies<sup>20,27</sup> have small sample sizes and both report a low number of hospitalizations.
     One study<sup>28</sup> reports a low prevalence of underlying asthma and one<sup>21</sup> does not report the prevalence.
- Three cohort studies<sup>7,25,34</sup> (N = 3,800) report no association between hospitalization and underlying asthma among COVID-19 patients.
  - One study<sup>7</sup> (N = 343) reports an effect measure suggesting no association between underlying asthma and hospitalization when adjusting for age, sex, race, COPD, and obesity (aOR 1.0 (95% CI: 0.34-3.28), p > 0.99). The study has a small sample size and reports a wide confidence interval, decreasing confidence in the finding.
  - One study<sup>25</sup> (N = 209) reports an adjusted effect measure suggesting no association between underlying asthma and hospitalization [aOR 1 (95% CI: 0.9-1.05), p = 0.9]. The study has a small sample size and does not report which variables are included in the model, decreasing confidence in the finding.
  - One study<sup>34</sup> (N = 3,248) reports an effect measure suggesting no association between underlying asthma and hospitalization when adjusting for age, sex, race, ethnicity, payor, smoking status, BMI, and Charles Comorbidity Index [aHR 0.99 (95% CI: 0.8-1.22), p = NR].
- Four studies<sup>12,14,23,26</sup> (N = 175,192) suggest that underlying asthma is associated with a decrease in hospitalization among COVID-19 patients. Three cohort studies<sup>12,14,23</sup> (N = 166,519) and one case-control study<sup>26</sup> (N = 8,673) report effect measures ranging from 0.28 (95% CI: 0.14-0.55) to 0.87 (95% CI: NR).
  - One study<sup>26</sup> has a high threat to internal validity and reports a confidence interval that includes the null and one study<sup>23</sup> reports a low number of hospitalizations, decreasing confidence in the findings.

#### Readmission

The evidence indicates an increase in readmission among COVID-19 patients with underlying asthma.

• Strength of Association: Two studies<sup>36,37</sup> report adjusted measures of association of 1.52 (95% CI: 1.04-2.22) and 1.7 (95% CI: 1.1-2.7).

- Precision of Association: Both<sup>36,37</sup> confidence intervals are wide.
- Consistency of Association: Results are consistent.
- Applicability of Association: Settings and populations were applicable.

Two studies $^{36,37}$  (N = 8,990) report data on underlying asthma and readmission among COVID-19 patients and both have a moderate threat to internal validity.

- Two cohort studies<sup>36,37</sup> (N = 8,990) report adjusted effect measures indicating underlying asthma is associated with an increase in readmission among COVID-19 patients.
  - One study<sup>36</sup> (N = 7,137) reports an effect measure indicating an increase in non-elective readmissions to the hospital during the first 30 days after being discharged when adjusting for age, Charlson Comorbidity Index score, diabetes, COPD, solid neoplasia, hypertension, dementia, duration of symptoms before admission, hemoglobin level and platelets count at admission, ground-glass infiltrate at admission, acute cardiac injury, acute kidney failure, and glucocorticoid treatment [aOR 1.52 (95% CI: 1.04-2.22), p = 0.031].
  - One study<sup>37</sup> (N = 1,853) reports an effect measure indicating an increase in subsequent hospital encounters within 30 days of initial discharge when adjusting for age at encounter, gender, race/ethnicity, parent hospital, month of diagnostic encounter, social vulnerability index, financial class, BMI, obesity class, medical history, surgical history, exposure history, symptoms screening, admission category, and therapy administered at initial encounter [aOR 1.7 (95% CI: 1.1-2.7), p = 0.03].

Table 3. Severity of underlying asthma examined for association with severe COVID-19 outcomes

| Outcome   | Results   |
|-----------|---|
| Mortality | Evidence is inconsistent and inconclusive on the association between asthma severity and mortality among COVID-19 patients with underlying asthma. Definitions used for asthma severity were heterogeneous across studies, limiting the conclusions that can be drawn from these results. |
|           | • Strength of Association: Eight studies <sup>2,9,34,45,63-66</sup> report adjusted measures of association ranging from 0.06 (95% CI: 0.001-2.06) to 3.62 (95% CI: 0.89-14.68).  |
|           | <ul> <li>Precision of Association: Confidence intervals are wide in five studies<sup>9,34,64-66</sup> and all eight report confidence intervals that include the null.</li> </ul>   |
|           | Consistency of Association: Results are inconsistent.   |
|           | <ul> <li>Applicability of Association: Settings and populations were applicable.</li> </ul>   |
|           | Eight studies <sup>2,9,34,45,63-66</sup> (N = 91,104) report mortality data that is stratified by asthma severity or examined in a subgroup analysis among COVID-19 patients with underlying asthma, and all have a moderate threat to internal validity.                                 |
|           | • Three cohort studies <sup>63,65,66</sup> (N = 14,862) suggest an increase in asthma severity is associated with an increase in mortality among COVID-19 patients with underlying asthma.  |

- One study<sup>65</sup> (N = 7,590) reports an effect measure suggesting an increase in mortality among COVID-19 patients with uncontrolled asthma when compared to those with controlled asthma [aOR 3.62 (95% CI: 0.89-14.68), p = 0.072].
   Uncontrolled asthma is defined as an asthma exacerbation requiring an emergency room visit in the past year. The study reports a wide confidence interval that includes the null, decreasing confidence in the results.
- One study<sup>66</sup> (N = 7,272) reports an effect measure suggesting an increase in mortality among COVID-19 patients with moderate to severe asthma compared to those with mild asthma [aOR 1.33 (95% CI: 0.54-3.30, p = 0.526]. Moderate to severe asthma is determined by prescribed medication. This study reports a wide confidence interval that includes the null, decreasing confidence in the results.
- One study<sup>63</sup> (N = NR) reports an increase in mortality for COVID-19 patients with recent oral corticosteroid (OCS) use, however there is no difference for those with no recent OCS use (recent OCS use: aHR 1.13 (95% CI: 1.01-1.26), p = NR; no recent OCS use: aHR 0.99 (0.93-1.05), p = NR]. This study uses COVID-19 patients without asthma as a comparison group.
- Two cohort studies<sup>2,45</sup> (N = 61,338) suggest no association between mortality and asthma severity among COVID-19 patients with underlying asthma.
  - One cohort study<sup>2</sup> (N = NR) reports effect measures suggesting no association between mortality and severe asthma or active asthma among COVID-19 patients when compared to patients without asthma [severe: aHR 1.08 (95% CI: 0.98-1.19), p = NR; active: aHR 1.05 (95% CI: 0.96-1.15), p = NR]. Severe asthma includes patients who were prescribed at least three different classes of medication for asthma in the previous year. Active asthma includes patients who had at least one prescription for asthma medication. This study uses COVID-19 patients without asthma as a comparison group.
  - One cohort study<sup>45</sup> (N = 61,388) reports effect measures suggesting no association between mortality and asthma among COVID-19 patients regardless of whether asthma is classified as active or inactive [active: aOR 0.98 (95% CI: 0.76-1.27), p = NR; inactive: aOR 0.83 (95% CI: 0.58-1.19), p = NR]. Active asthma is defined as any scheduled or unscheduled clinical visit with an asthma diagnosis code in the 12 months prior to a COVID-19 diagnosis. This study uses COVID-19 patients without asthma as the comparison group.
- Three cohort studies<sup>9,34,64</sup> (N = 14,904) suggest asthma severity is associated with a decrease in mortality among COVID-19 patients with underlying asthma.
  - One study<sup>9</sup> (N = 7,590) reports effect measures suggesting a decrease in mortality among COVID-19 patients with more severe asthma. Patients are classified based on asthma medications used for the past year. The first step includes SABA; the second includes ICS, LTRA or xanthine; the third includes ICS/LABA alone, ICS with LTRA or ICS with xanthine; the fourth includes ICS/LABA with LAMA, ICS/LABA with LTRA, or ICS/LABA with xanthine; and the most severe category includes oral corticosteroid with a duration longer than 90 days. The odds of mortality decreases for patients categorized in steps 2 through 5 when compared to those in step 1 using SABA, however the confidence intervals are wide and include the null, decreasing confidence in the results.

- One study<sup>64</sup> (N= 4,066) reports adjusted effect measures suggesting a decrease in mortality among COVID-19 patients with asthma compared to those without asthma, however the decrease is greater among those with severe asthma defined as patients using ICS/LABA with LAMA, ICS/LABA with LTRA, ICS/LABA with xanthine, or corticosteroids for over 90 days within previous two years [mild: aOR 0.85 (95% CI: 0.45-1.6), p = 0.605; severe: aOR 0.7 (95% CI: 0.13-3.68), p = 0.672].
- One study<sup>34</sup> (N = 3,248) reports an adjusted effect measure suggesting a decrease in mortality among COVID-19 patients with allergic asthma compared to those with non-allergic asthma [aHR 0.82 (95% CI: 0.24-2.75)]. Allergic asthma includes those with a history of allergic rhinitis in the past year or those on therapy with oral antihistamine, leukotriene modifier, intranasal corticosteroid spray, or intranasal antihistamine in the past year. This study has a low number of deaths and a wide confidence interval that includes the null, decreasing confidence in the finding.

#### **ICU** admission

The evidence is inconclusive on the association between asthma severity and ICU admission among COVID-19 patients with underlying asthma. Definitions used for asthma severity were heterogeneous across studies, limiting the conclusions that can be drawn from these results.

- Strength of Association: Three studies<sup>2,9,45</sup> report adjusted measures of association ranging from 0.06 (95% CI: 0.002-1.85) to 1.47 (95% CI: 1.14-1.89).
- Precision of Association: One study<sup>9</sup> has wide confidence intervals and two<sup>9,45</sup> include the null.
- Consistency of Association: Results are inconsistent.
- Applicability of Association: Settings and populations were applicable.

Three studies<sup>2,9,45</sup> (N = 68,928) report ICU admission data that is stratified by asthma severity or examined in a subgroup analysis among COVID-19 patients with underlying asthma and all have a moderate threat to internal validity.

- Two cohort studies<sup>2,45</sup> (N = 61,338) suggest that asthma severity is associated with an increase in ICU admission among COVID-19 patients with asthma. Each study defines asthma severity differently, decreasing confidence in the results.
  - One study<sup>2</sup> (N = NR) reports effect measures indicating severe asthma and active asthma are associated with an increase in ICU admission when compared to those without asthma [severe: aHR 1.30 (95% CI: 1.08-1.58), p = NR; active: aHR 1.34 (95% CI: 1.14-1.58), p = NR]. Severe asthma includes patients who were prescribed at least three different classes of medication for asthma in the previous year, while active asthma includes patients who had at least one prescription for asthma medication. This study uses COVID-19 patients without asthma as the comparison group.
  - One study<sup>45</sup> (N = 61,388) reports an effect measure indicating active asthma is associated with an increase in ICU admission among COVID-19 patients while there was no association for those with inactive asthma [active: aOR 1.47 (95% CI: 1.14-1.89), p = NR; inactive: aOR 0.81 (95% CI: 0.56-1.2), p = NR]. Active asthma is defined as any scheduled or unscheduled clinical visit with an asthma diagnosis code in the 12 months prior to a COVID-19 diagnosis. This study used COVID-19 patients without asthma as the comparison group.

- One cohort study<sup>9</sup> (N = 7,590) suggests an increase in asthma severity is associated with a decrease in ICU admission among COVID-19 patients with underlying asthma.
  - One study<sup>9</sup> (N = 7,590) reports effect measures suggesting a decrease in ICU admission among COVID-19 patients with more severe asthma. Patients are classified based on asthma medications used for the past year. The first step includes SABA; the second includes ICS, LTRA or xanthine; the third includes ICS/LABA alone, ICS with LTRA or ICS with xanthine; the fourth includes ICS/LABA with LAMA, ICS/LABA with LTRA, or ICS/LABA with xanthine; and the most severe category includes oral corticosteroid with a duration longer than 90 days. The odds of ICU admission decreases for patients categorized in steps 2-5 when compared to those in step 1 using SABA, however the confidence intervals are wide and include the null, decreasing confidence in the results.

#### Ventilation

The evidence is inconclusive on the association between asthma severity and ventilation among COVID-19 patients with underlying asthma. Definitions used for asthma severity were heterogeneous across studies, limiting the conclusions that can be drawn from these results.

- Strength of Association: Two studies<sup>34,45</sup> report adjusted measures of association ranging from 0.47 (95% CI: 0.22-1.01) to 85.2 (95% CI: 5.55-1310).
- Precision of Association: One study<sup>34</sup> reports a wide confidence interval and both report confidence intervals that include the null.
- Consistency of Association: Results are inconsistent.
- Applicability of Association: Settings and populations were applicable.

Two studies $^{34,45}$  (N = 64,586) report ventilation data by that is stratified by asthma severity or examined in a subgroup analysis among COVID-19 patients with underlying asthma and both have a moderate threat to internal validity.

- Two cohort studies<sup>34,45</sup> suggests that asthma severity is associated with an increase in ventilation among COVID-19 patients with underlying asthma.
  - One study<sup>45</sup> (N = 61,338) reports an effect measure indicates active asthma is associated with an increase in ventilation among COVID-19 patients while there was no association for those with inactive asthma [active: aOR 1.49 (95% CI: 1.21-1.83), p = NR; inactive: aOR 0.83 (95% CI: 0.61-1.12), p = NR]. Active asthma is defined as any scheduled or unscheduled clinical visit with an asthma diagnosis code in the 12 months prior to a COVID-19 diagnosis. This study uses COVID-19 patients without asthma as the comparison group.
  - One study<sup>34</sup> (N=3,248) reports an effect measure suggesting severe asthma is associated with an increase in mechanical ventilation when compared to patients with non-severe asthma (aHR 85.2 (95% CI: 5.55-1310)). Severe asthma includes patients who used asthma biologics in past year, received oral corticosteroids three or more times in past year, or received theophylline in the past year. However, the study reports a decrease in mechanical ventilation among COVID-19 patients with allergic asthma compared to those with non-allergic asthma [aHR 0.65 (95% CI: 0.28-1.51)]. Allergic asthma includes those with a history of allergic rhinitis in the past year or those on therapy with oral antihistamine, leukotriene

modifier, intranasal corticosteroid spray, or intranasal antihistamine in the past year. This study has a wide confidence interval that includes the null and reports a low number of ventilations, decreasing confidence in the findings.

### Hospitalization

The evidence suggests asthma severity is associated with an increase in hospitalization among COVID-19 patients with underlying asthma, while allergic asthma is associated with a decrease in hospitalization. However, definitions used for asthma severity are heterogeneous across studies, limiting the conclusions that can be drawn from these results.

- Strength of Association: Six studies<sup>2,22,34,41,45,62</sup> report adjusted measures of association ranging from 0.52 (95% CI: 0.28-0.91) to 1.99 (95% CI: 0.82-4.79).
- Precision of Association: Two studies<sup>34,41</sup> report wide confidence intervals and three<sup>34,41,45</sup> report confidence intervals that include the null.
- Consistency of Association: Results are inconsistent.
- Applicability of Association: Settings and populations were applicable.

Six cohort studies<sup>2,22,34,41,45,62</sup> (N = 89,578) report hospitalization data that is stratified by asthma severity or examined in a subgroup analysis among COVID-19 patients with underlying asthma among COVID-19 patients with underlying asthma and all six have a moderate threat to internal validity.

- Four studies<sup>2,34,45,62</sup> (N = 79,424) indicate that asthma severity is associated with an increase in hospitalization among COVID-19 patients with underlying asthma. Four studies report adjusted effect measures ranging from 1.26 (95% CI: 1.2-1.33) to 1.99 (95% CI: 0.82-4.79). In one study,<sup>2</sup> severe asthma includes patients who were prescribed at least three different classes of medication for asthma in the previous year while active asthma includes patients who had at least one prescription for asthma medication. Another study<sup>62</sup> determines severity by the number of general practitioner-managed asthma exacerbations in the past five years, which are defined as a prescription for a short course of oral corticosteroids. One study<sup>45</sup> defines active asthma as any scheduled or unscheduled clinical visit with an asthma diagnosis code in the 12 months prior to a COVID-19 diagnosis. In another,<sup>34</sup> severe asthma includes patients who used asthma biologics in the past year, received oral corticosteroids three or more times in the past year, or received theophylline in the past year.
  - One study<sup>34</sup> reports a wide confidence interval that includes the null, decreasing confidence in the finding. Three studies<sup>2,34,45</sup> use COVID-19 patients without asthma as comparison groups.
- Three studies<sup>22,34,41</sup> (N = 13,482) suggest that severe and allergic asthma is associated with a decrease in hospitalization among COVID-19 patients with underlying asthma.
  - One study<sup>22</sup> (N = 5,596) reports an adjusted effect measure suggesting a decrease in hospitalization among COVID-19 patients with allergic asthma compared to those with non-allergic asthma [aOR 0.52 (95% CI: 0.28-0.91), p = 0.026].
     Allergic asthma includes allergic rhinitis or atopic dermatitis.
  - One study<sup>41</sup> (N = 4,558) reports effect measures suggesting hospitalization is lowest among patients with severe asthma as categorized by ICD-9 and ICD-10 codes [aOR 0.58 (95% CI: 0.13-2.59)]. There is a decrease in hospitalization among patients with mild persistent asthma [(aOR 0.77 (95% CI: 0.28-2.13)], however there is no difference for patients with mild intermittent or moderate persistent asthma [mild intermittent: aOR 0.92 (95% CI: 0.55-1.53); moderate persistent:

- aOR 1.0 (95% CI: 0.42-2.37)]. The study has wide confidence intervals that include the null and reports a low number of hospitalizations among patients with mild persistent asthma, moderate persistent asthma, and severe asthma, decreasing confidence in the findings.
- One study<sup>34</sup> (N = 3,328) reports an adjusted effect measure suggesting a decrease in hospitalization among COVID-19 patients with allergic asthma compared to those with non-allergic asthma [aHR 0.86 (95% CI: 0.64-1.16)]. Allergic asthma includes those with a history of allergic rhinitis in the past year or those on therapy with oral antihistamine, leukotriene modifier, intranasal corticosteroid spray, or intranasal antihistamine in the past year. This study has a wide confidence interval that includes the null, decreasing confidence in the findings.

Table 4. Treatment for underlying asthma examined for association with severe COVID-19 outcomes

| Outcome   | Results   |
|-----------|---|
| Mortality | The evidence is inconclusive on the association between asthma treatment and mortality among COVID-19 patients with underlying asthma. Definitions used for asthma treatment are heterogeneous across studies, limiting the conclusions that can be drawn from these results. |
|           | • Strength of Association: Four studies <sup>39,45,50,67</sup> report adjusted effect measures ranging from 0.23 (95% CI: 0.05-1.1) to 2 (95% CI: 1.18-3.4).  |
|           | <ul> <li>Precision of Association: Two studies<sup>50,67</sup> report wide confidence intervals and all four report confidence intervals that include the null.</li> </ul>  |
|           | <ul> <li>Consistency of Association: Results are inconsistent.</li> </ul>   |
|           | <ul> <li>Applicability of Association: Settings and populations were applicable.</li> </ul>   |
|           | Four studies <sup>39,45,50,67</sup> (N = 146,088) report mortality data that is stratified by asthma treatment or examined in a subgroup analysis among COVID-19 patients with underlying asthma and all four have a moderate threat to internal validity.                    |
|           | • Two cohort studies <sup>50,67</sup> (N = 9,287) suggest steroid use is associated with an increase in mortality among COVID-19 patients with underlying asthma.   |
|           | <ul> <li>One study<sup>67</sup> (N = 8,242) reports adjusted effect measures suggesting steroid use is associated with an increase in</li> </ul>  |
|           | mortality among COVID-19 patients with underlying asthma [aHR 1.16 (95% CI: $0.81-1.64$ ), $p = 0.418$ ]. When stratifying  |
|           | on recency, data suggests an increase in risk for those with recent steroid use in the previous 120 days, however there is  |
|           | no association for asthmatics with former steroid use in the previous 120 to 365 days [recent use: aHR 1.4 (95% CI: 0.92-   |
|           | 2.15), p = 0.12; former use: aHR 0.93 (95% CI: 0.57-1.51), p = 0.769]. When stratified by the number of steroid   |
|           | prescriptions, data indicates an increase in mortality among those with three or more steroid prescriptions but not for   |
|           | those with one or two prescriptions [one: aHR 0.91 (95% CI: 0.53-1.56, p = 0.733; two: aHR 0.86 (95% CI: 0.42-1.78), p =  |
|           | 0.694; three or more: aHR 1.64 (95% CI: 1.05-2.59), p = 0.032]. There is no association between the use of biologics and  |

- mortality among asthmatics with COVID-19. This study reports wide confidence intervals that include the null, decreasing confidence in the findings.
- One cohort study<sup>50</sup> (N = 1,045) report adjusted effect measures suggesting a smaller decrease in mortality among COVID-19 patients with underlying asthma on ICS than those not on ICS when compared to patients without asthma. While data suggests a decrease in mortality among COVID-19 patients with underlying asthma regardless of documented use of ICS in the previous seven days, the decrease appears greater among those not on ICS (ICS: aOR 0.46 (95% CI: 0.18-2.2), p = NR; no ICS: aOR 0.23 (95% CI: 0.05-1.1), p = 0.051). This study reports a low number of deaths and wide confidence intervals that include the null, decreasing confidence in the findings.
- Two cohort studies<sup>39,45</sup> (N = 136,801) suggest asthma medication is associated with a decrease in mortality among COVID-19 patients with underlying asthma.
  - One study<sup>39</sup> (N=75,463) reports effect measures suggesting asthma therapies are associated with a decrease in mortality when adjusting for severity on admission, age, and comorbidities. While there is no difference in mortality for COVID-19 patients aged 16 to 49 who are on SABA, ICS, or ICS with LABA treatments when compared to those without asthma, there is an increase for those with underlying asthma who were not on any asthma therapy [SABA: aHR 1.01 (95% CL 0.62-1.65), p = 0.964; ICS: aHR 0.99 (95% CI: 0.65-1.49), p = 0.956; ICS with LABA: aHR 1.03 (95% CI: 0.68-1.55), p = 0.898; no therapy: aHR 1.21 (95% CI: 0.75-1.95), p = 0.435]. For patients aged 50 and older, there is a decrease in mortality among COVID-19 patients with underlying asthma on ICS treatment when compared to those with no respiratory disease, while there is no difference in mortality for those with asthma not on ICS treatment [ICS: aHR 0.88 (95% CI: 0.82-0.94), p < 0.001; no ICS: aHR 0.97 (95% CI: 0.9-1.05), p = 0.455].
  - One study<sup>45</sup> (N = 61,338) reports adjusted effect measures suggesting there is a decrease in mortality among COVID-19 patients with either active asthma or inactive asthma when patients are on medication including bronchodilators, leukotriene receptor antagonists, or corticosteroids [active asthma: aHR 0.86 (95% CI: 0.63-1.18), p = NR; inactive asthma: aHR 0.77 (95% CI: 0.47-1.27), p = NR]. There is an increase in mortality for COVID-19 patients with active asthma without medication and no association for patients with inactive asthma without medication [active asthma: aHR 1.33 (95% CI: 0.87-2.05), p = NR; inactive asthma: aHR 0.91 (95% CI: 0.54-1.51), p = NR]. This study reports confidence intervals that include the null, decreasing confidence in the findings.

#### **ICU** admission

The evidence is inconclusive on the association between asthma treatment and ICU admission among COVID-19 patients with underlying asthma. Aggregation indices cannot be measured with only one study which was found to have a moderate threat to internal validity.

- One cohort study<sup>45</sup> (N = 61,338) suggests asthma treatment is associated with a decrease in ICU admission among COVID-19 patients with active asthma.
  - One study<sup>45</sup> (N = 61,338) reports adjusted measures of effect suggesting medications including bronchodilators, leukotriene receptor antagonists, or corticosteroids are associated with a decrease in ICU admission for COVID-19 patients with active asthma. When compared to those without asthma, the odds of ICU admission is greater among

COVID-19 patients with active asthma not on medication in the past 12 months than for those on medication [medication: aOR 1.2 (95% CI: 0.89-1.62), p = NR; no medication: aOR 2.75 (95% CI: 1.77-4.27), p = NR]. However, for inactive asthma the data suggest no association between medication and ICU admission [medication: aOR 0.88 (95% CI: 0.53-1.45), p = NR; no medication: aOR 0.74 (95% CI: 0.41-1.32), p = NR].

#### Ventilation

The evidence is inconclusive on the association between asthma treatment and ventilation among COVID-19 patients with underlying asthma. Aggregation indices cannot be measured with only one study which was found to have a moderate threat to internal validity.

- One cohort study $^{45}$  (N = 61,338) suggests asthma treatment is associated with a decrease in ventilation among COVID-19 patients with underlying active asthma.
  - The study<sup>45</sup> (N = 61,338) reports adjusted measures of effect suggesting medications including bronchodilators, leukotriene receptor antagonists, or corticosteroids are associated with a decrease in ventilation for COVID-19 patients with active asthma. When compared to those without asthma, the odds of ventilation is greater among COVID-19 patients with active asthma not on medication in the past 12 months than for those on medication [medication: aOR 1.36 (95% CI: 1.08-1.72), p = NR; no medication: aOR 2.06 (95% CI: 1.37-3.1), p = NR]. However, for inactive asthma the data suggested no association between medication use and ventilation [medication: aOR 0.93 (95% CI: 0.63-1.14), p = NR; no medication: aOR 0.71 (95% CI: 0.45-1.14), p = NR].

### Hospitalization

The evidence is inconclusive on the association between asthma treatment and hospitalization among COVID-19 patients with underlying asthma. Definitions used for asthma treatment were heterogeneous across studies, limiting the conclusions that can be drawn from these results.

- Strength of Association: Three studies<sup>41,45,62</sup> report adjusted measures of association ranging from 0.59 (95% CI: 0.21-1.69) to 2.36 (95% CI: 0.273-20.4).
- Precision of Association: Two studies<sup>41,62</sup> report wide confidence intervals and all three studies report confidence intervals that include the null.
- Consistency of Association: Results are inconsistent.
- Applicability of Association: Settings and populations were applicable.

Three cohort studies  $^{41,45,62}$  (N = 80,734) reported hospitalization data that are stratified by asthma treatment or examined in a subgroup analysis among COVID-19 patients with underlying asthma and three have a moderate threat to internal validity.

- Two studies study $^{41,62}$  (N = 19,396) suggest inhaled corticosteroids, montelukast, and biologics are associated with an increase in hospitalization among COVID-19 patients with underlying asthma.
  - One study<sup>62</sup> (N = 14,838) reports adjusted measures of effect indicating regular inhaled corticosteroids (ICS) is associated with an increase in hospitalization [regular ICS: aHR 1.27 (95% CI: 1.10-1.61), p <0.05; regular ICS with add-on: aHR 1.63 (95% CI: 1.37-1.94), p <0.001]. There is no association for SABA treatment or intermittent ICS [SABA only: aHR 0.94 (95%</li>

- CI: 0.75-1.17), p = 0.56; intermittent ICS: aHR 0.9 (95% CI: 0.67-1.21), p = 0.49], however there is an increase for intermittent ICS with an additional asthma maintenance medication [aHR 2.0 (95% CI: 1.43-2.79), p<0.001].
- One study<sup>41</sup> (N = 4,558) reports adjusted measures of effect suggesting inhaled corticosteroids (ICS), montelukast, and biologics are associated with an increase in hospitalization among COVID-19 patients with underlying asthma [ICS: aOR 1.51 (95% CI: 0.9-2.56), p = NR; montelukast: aOR 1.36 (95% CI: 0.72-2.54), p = NR; biologics: aOR 2.36 (95% CI: 0.27-20.4), p = NR]. Both antihistamines and SCIT are associated with a decrease in hospitalization, while there was no association for oral corticosteroids [antihistamines: aOR 0.88 (95% CI: 0.54-1.43), p = NR; SCIT: aOR 0.8 (95% CI: 0.2-3.22), p = NR; oral corticosteroids: aOR 1.04 (95% CI: 0.68-1.6), p = NR]. When stratifying inhaled corticosteroids by dose, data suggest no association with hospitalization regardless of dose among COVID-19 patients with underlying asthma [low: aOR 1.64 (95% CI: 0.17-15.06), p = NR; medium: aOR 1.53 (95% CI: 0.51-4.53), p = NR; high: aOR 0.59 (95% CI: 0.21-1.69), p = NR]. This study reports wide confidence intervals that include the null, decreasing confidence in the findings.
- One cohort study<sup>45</sup> (N = 61,338) suggests asthma treatment is associated with a decrease in hospitalization among COVID-19 patients with underlying active asthma.
  - One study<sup>45</sup> (N = 61,338) reports adjusted measures of effect indicating medications including bronchodilators, leukotriene receptor antagonists, or corticosteroids are associated with a decrease in hospitalization for COVID-19 patients with active asthma. When compared to those without asthma, the odds of hospitalization are greater among COVID-19 patients with active asthma not on medication in the past 12 months than for those on medication [medication: aOR 1.56 (95% CI: 1.35-1.81), p = NR; no medication: aOR 2.14 (95% CI: 1.62-2.82), p = NR]. However, for inactive asthma the measures of association suggest no difference in the adjusted odds of hospitalization for COVID-19 patients with or without medication [medication: aOR 1.02 (95% CI: 0.8-1.28), p = NR; no medication: aOR 0.89 (95% CI: 0.68-1.15), p = NR].

Table 5. The association between asthma and other comorbidities and severe COVID-19 outcomes

| Outcome   | Results   |
|-----------|---|
| Mortality | <ul> <li>The evidence suggests comorbidities are associated with an increase in mortality among COVID-19 patients with underlying asthma.</li> <li>Strength of Association: Two studies<sup>41,67</sup> report adjusted measures of association ranging from 1.12 (95% CI: 0.79-1.59) to 3.2 (95% CI: 1.32-7.79).</li> <li>Precision of Association: One study<sup>41</sup> report wide confidence intervals and one<sup>67</sup> reports confidence intervals that includes the null.</li> <li>Consistency of Association: Results are consistent.</li> <li>Applicability of Association: Settings and populations were applicable.</li> </ul> |

Two studies<sup>41,67</sup> (N = 12,800) report data on comorbidities and mortality among COVID-19 patients with underlying asthma and both have a moderate threat to internal validity. • Two cohort studies<sup>41,67</sup> (N = 12,800) suggest that comorbidities are associated with an increase in mortality among COVID-19 patients with underlying asthma. One study<sup>67</sup> (N = 8,242) reports adjusted effect measures indicating that diabetes and ischemic heart disease are associated with an increase in mortality, and suggestive that hypertension and obesity are associated with an increase in mortality among COVID-19 patients with underlying asthma [diabetes: aHR 1.73 (95% CI: 1.22-2.47), p = 0.002; ischemic heart disease: aHR 1.85 (95% CI: 1.31-2.6), p < 0.001; hypertension: aHR 1.44 (95% CI: 0.87-2.37), p = 0.154; obesity: aHR 1.12 (95% CI: 0.79-1.59), p = 0.514]. One study<sup>41</sup> (N=4,558) reports adjusted effect measures suggesting that congestive heart failure (CHF) and COPD are associated with an increase in mortality among COVID-19 patients with underlying asthma [CHF: aOR 2.29 (95% CI: 1.009-5.22), p = 0.2; COPD: aOR 3.2 (95% CI: 1.32-7.79), p = 0.06]. Hypertension, diabetes, and chronic kidney disease are not found to affect mortality among admitted COVID-19 patients with underlying asthma. The study has wide confidence intervals, decreasing confidence in the findings. Hospitalization The evidence is inconclusive on the association between comorbidities and hospitalization among COVID-19 patients with underlying asthma. Aggregation indices cannot be measured with only one study which was found to have a moderate threat to internal validity. • One cohort study<sup>33</sup> (N = 15,690) suggests there is no association between BMI score and hospitalization among COVID-19 patients with underlying asthma.

One study<sup>33</sup> (N = 15,690) reports adjusted effect measures suggesting no difference in the association between

hospitalization and underlying asthma across BMI score [BMI <30: aRR 1.09 (95% CI: 0.97-1.22), p = 0.13; BMI ≥30: aRR

Table 6. The association between asthma and risk markers and severe COVID-19 outcomes

1.11 (95% CI: 0.98-1.25), p = 0.111].

| Outcome   | Results  |
|-----------|--|
| Mortality | <ul> <li>The evidence is inconclusive on the association between risk markers and mortality among COVID-19 patients with underlying asthma.</li> <li>Strength of Association: Five studies<sup>30,31,45,67,69</sup> report adjusted measures of association ranging from 0.73 (95% CI: 0.52-1.02) to 1.88 (95% CI: 1.43-2.48).</li> <li>Precision of Association: Three studies<sup>31,45,67</sup> report wide confidence intervals and all five report confidence intervals that</li> </ul> |
|           | <ul> <li>included the null.</li> <li>Consistency of Association: Results are consistent.</li> </ul>  |

Applicability of Association: Settings and populations were applicable.

Five studies<sup>30,31,45,67,69</sup> reported mortality data that is stratified by risk marker or examined in a subgroup analysis among COVID-19 patients with underlying asthma, and were found to have a moderate threat to internal validity.

- Three studies<sup>30,45,67</sup> (N = 113,045) report data on age, mortality, and underlying asthma among COVID-19 patients. Two studies<sup>30,45</sup> report adjusted effect measures suggesting younger age is associated with an increase in mortality among COVID-19 patients with active asthma<sup>45</sup> and pediatric COVID-19 patients with underlying asthma.<sup>30</sup> However, there was no difference in the odds of mortality across age groups among COVID-19 patients with inactive asthma,<sup>45</sup> and one study<sup>67</sup> reports that mortality increases with each year increase in age.
  - One study<sup>45</sup> reports wide confidence intervals and two<sup>30,45</sup> report confidence intervals that include the null, decreasing confidence in the results.
- Two studies<sup>67,69</sup> (N = 8,242) report data on sex, mortality, and underlying asthma among COVID-19 patients. One study<sup>67</sup> reports an adjusted effect measure suggesting male sex is associated with an increase in mortality among COVID-19 patients with underlying asthma, however another study<sup>69</sup> reports adjusted effect measures suggesting female sex is associated with an increase.
  - One study<sup>67</sup> reports a wide confidence interval and one<sup>69</sup> reports a confidence interval that includes the null, decreasing confidence in the results.
- Two studies<sup>31,67</sup> (N = 20,172) report data on race or ethnicity, mortality, and underlying asthma among COVID-19 patients. One study<sup>31</sup> reports adjusted effect measures suggesting an increase in mortality for non-Hispanic Asians with underlying asthma, but not for non-Hispanic White, non-Hispanic Black, or Hispanic patients with underlying asthma when compared to patients without underlying asthma. Another study<sup>67</sup> reports no difference among patients with underlying asthma when comparing Arab ethnicity to Jewish ethnicity. One study<sup>67</sup> reports a decrease in mortality for patients who reported having ever smoked when compared to those who had never smoked.
  - One study<sup>31</sup> reports wide confidence intervals and both<sup>31,67</sup> report confidence intervals that include the null, decreasing confidence in the results.

#### **ICU** admission

The evidence is inconclusive on the association between risk markers and ICU admission among COVID-19 patients with underlying asthma. Aggregation indices cannot be measured with only one study which was found to have a moderate threat to internal validity.

- One cohort study<sup>45</sup> (N = 61,338) suggests younger age is associated with an increase in ICU admission among COVID-19 patients with underlying asthma.
  - One study<sup>45</sup> reports adjusted effect measures suggesting that while active asthma is associated with an increase in ICU admission regardless of age, the association decreases with age [age 18-34: aOR 1.86 (95% CI: 0.76-4.55), p = NR; age 35-64: aOR 1.52 (95% CI: 1.07-2.15), p = NR; age  $\geq$ 65: 1.29 (95% CI: 0.86-1.94), p = NR]. Similarly, there is no association

between inactive asthma and ICU admission among COVID-19 patients aged 18 to 34, however data suggest there could be a decrease in ICU admission for those aged 35 and older [age 18-34: aOR 0.99 (95% CI: 0.23-4.17), p = NR; age 35-64: aOR 0.78 (95% CI: 0.46-1.33), p = NR; age  $\geq$ 65: aOR 0.87 (95% CI: 0.47-1.59), p = NR].

#### Ventilation

The evidence is inconclusive on the association between risk markers and ventilation among COVID-19 patients with underlying asthma. Aggregation indices cannot be measured with only one study which was found to have a moderate threat to internal validity.

- One cohort study<sup>45</sup> (N = 61,338) suggests younger age is associated with an increase in ventilation among COVID-19 patients with underlying asthma.
  - One study<sup>45</sup> reported adjusts effect measures suggesting that while active asthma is associated with an increase in ventilation regardless of age, the measure of association decreases with age [age 18-34: aOR 1.74 (95% CI: 0.8-3.77), p = NR; age 35-64: aOR 1.6 (95% CI: 1.21-2.13), p = NR; age ≥65: 1.27 (95% CI: 0.91-1.76), p = NR]. Similarly, there is no association between inactive asthma and ICU admission among COVID-19 patients aged 18 to 64, however the data suggest a decrease in ICU admission for those aged 65 and older [age 18-34: aOR 0.92 (95% CI: 0.28-3.01), p = NR; age 35-64: aOR 0.97 (95% CI: 0.66-1.43), p = NR; age ≥65: aOR 0.66 (95% CI: 0.39-1.11), p = NR].

### Hospitalization

The evidence suggests female sex is associated with an increase in hospitalization among COVID-19 patients with underlying asthma. Evidence is inconclusive on the association between other risk markers and hospitalization.

- Strength of Association: Six studies<sup>31,33,41,45,68,69</sup> report measures of association ranging from 0.2 (95% CI: 0.12-0.34) to 2.21 (95% CI: 1.53-3.2).
- Precision of Association: Four studies<sup>31,41,45,68</sup> have wide confidence intervals and five<sup>31,33,41,45,68</sup> report confidence intervals that include null.
- Consistency of Association: Results are inconsistent.
- Applicability of Association: Settings and populations were applicable.

Six studies $^{31,33,41,45,68,69}$  (N = 93,623) report stratified hospitalization data by risk markers or subgroup analyses among COVID-19 patients with underlying asthma and have a moderate threat to internal validity.

- Three studies<sup>33,41,45</sup> (N = 81,586) report data on age, hospitalization, and underlying asthma among COVID-19 patients. One study<sup>45</sup> reports adjusted effect measures suggesting younger age is associated with an increased odds of hospitalization among COVID-19 patients with underlying asthma. However, another study<sup>41</sup> reports adjusted effect measures indicating that older age is associated with an increase in hospitalization and one<sup>33</sup> reports no association between age and hospitalization among COVID-19 patients with underlying asthma.
  - One study<sup>45</sup> reports wide confidence intervals and two<sup>33,45</sup> report confidence intervals that include the null, decreasing confidence in the findings.

- Three studies<sup>33,41,69</sup> (N = 20,248) report adjusted effect measures indicating female sex is associated with an increase in hospitalization among COVID-19 patients with underlying asthma.
  - o One study<sup>33</sup> reports a confidence interval that includes the null, decreasing confidence in the finding.
- Three studies<sup>31,33,41</sup> (N = 32,178) reports on race or ethnicity, hospitalization, and underlying asthma among COVID-19 patients. All three report adjusted effect measures suggesting non-Hispanic White ethnicity is associated with an increase in hospitalization when either compared with other racial or ethnic groups<sup>41</sup> or when stratified by race or ethnicity.<sup>31,33</sup> One study<sup>31</sup> also reports an increase among non-Hispanic Asian patients with underlying asthma when compared to patients without underlying asthma.
  - Two studies<sup>31,41</sup> report wide confidence intervals and all three report confidence intervals that include the null, decreasing confidence in the findings.
- Three studies<sup>33,41,68</sup> (N = 20,355) report on smoking status, hospitalization, and underlying asthma among COVID-19 patients. One study<sup>41</sup> reports an adjusted effect measure suggesting current smokers have lower odds of hospitalization than COVID-19 patients with underlying asthma who reported never smoking. However, another study (Beken 2021) reports an increase in the odds of hospitalization for those with passive tobacco exposure and one<sup>33</sup> reports no difference across smoking status.
  - Two studies<sup>41,68</sup> report wide confidence intervals and all three report confidence intervals that include the null, decreasing confidence in the findings. One study<sup>68</sup> has a small sample size.

| Study   | Population and Setting   | Intervention | Definitions  | Outcomes  |
|---|--|--------------|--|---|
| Retrospective cohort  Study Objective: To analyze the relationship between asthma and COVID-19 by identifying the factors predisposing to inpatient admission in our asthmatic population, and by comparing the mortality risk among admitted patients with only asthma and those with other coexistent chronic conditions, which have been shown to be unique risk factors for severe complications of COVID-19.  IVA Score: 24 (moderate) | Setting  Study dates: March 14 - April 27, 2020  Inclusion criteria: All adult patients (≥18 years old) who tested positive for SARS-CoV-2 infection by PCR at study institution during study dates were identified by a software application that stores EHR data. All patients who presented to the emergency department for COVID-19 symptoms and who had also been seen at least once in the study healthcare system within previous 10 years were included in analysis.  Exclusion criteria: NR |              | Moderate persistent asthma: ICD9/10 J45.40, J45.41, J45.42 Severe asthma: ICD9/10 J45.50, J45.51  Strength of inhaled corticosteroids (ICS): strength of daily dose inhaler based on last prescription found in chart within last year before COVID-19 infection; categorized as low, medium, or high dose  Clinical Marker: Prior eosinophilia: patients with mean AEC ≥150 cells/μL Increasing eosinophilia: admitted patients with eosinopenia in whom AEC increased to a peak ≥150 cells/μL  Treatment/ Associated Therapy: ICS: asthma patients with prescription for ICS within the year prior Oral corticosteroids: asthma patients with prescription for oral corticosteroids within the year prior Montelukast: asthma patients with prescription for montelukast within the year prior Antihistamines: asthma patients with prescription for antihistamines within the year prior Subcutaneous immunotherapy (SCIT): asthma patients with prescription for SCIT within the prior 3 years Biologics: asthma patients with prescription for biologics within the prior 3 years  Outcome Definitions: Mortality: mortality risk in admitted patients ICU admission: NR Intubation: NR | • aOR: 1.41 (95% CI: 0.28-7.12), p=0.6 • Asthma alone: 66/358 (18.4%) • No comorbidities: 10/74 (13.5%)  COPD vs. Asthma: • aOR: 0.87 (95% CI: 1.15-3.04), p=0.06 • COPD, no asthma: n=NR/N=NR (48.3%) • Asthma alone: 66/358 (18.4%) • p=0.01  Hospitalization, n*/N (%): Asthma: • Admitted: 749/951 (78.8%) • Not admitted: 202/951 (21.2%)  Severity of Condition: Hospitalization among all asthmatics, n*/N (%): Mild intermittent asthma: • aOR: 0.92 (95% CI: 0.55-1.53): 0.92 (95% CI: 0.55-1.53) • Admitted: 75/581 (12.9%) • Not admitted: 28/156 (17.9%) • p=0.76  Mild persistent asthma: • aOR: 0.77 (95% CI: 0.28-2.13) • Admitted: 15/581 (2.6%) • Not admitted: 6/156 (3.8%) • p=0.62  Moderate persistent asthma: • aOR: 1.0 (95% CI: 0.42-2.37) • Admitted: 25/581 (4.3%) • Not admitted: 8/156 (5.1%) • p=0.99  Severe asthma: • aOR: 0.58 (95% CI: 0.13-2.59) • Admitted: 5/581 (0.9%) • Not admitted: 3/156 (1.9%) • p=0.48  Low dose of ICS: • aOR: 1.64 (95% CI: 0.17-15.06) • Admitted: 8/N=NR (7%) • Not admitted: 1/N=NR (4.8%) • p=0.66 |
