Laboratory Outreach Communication System (LOCS) Call

Monday, July 15, 2024, at 3:00 P.M. ET

- **Welcome**
 - Sean Courtney, CDC Division of Laboratory Systems
- **Situational Update and Response to the Highly Pathogenic Avian Influenza A(H5N1) Outbreak in U.S. Dairy Cattle**
 - Todd Davis, CDC Influenza Division
- **CDC Efforts to Expand Testing Capacity and Enhance Surveillance**
 - Sean Courtney, CDC Division of Laboratory Systems
- **BD Update**
 - Chris Beddard, BD Life Sciences
- **CDC Culture Quality Tools**
 - Jake D. Bunn, CDC Division of Laboratory Systems
- **Blood Culture Utilization**
 - Valeria Fabre, Johns Hopkins University

About DLS

Vision

Exemplary laboratory science and practice advance clinical care, public health, and health equity.

Four Goal Areas

Quality Laboratory Science

- Improve the quality and value of laboratory medicine for better health outcomes and public health surveillance

Highly Competent Laboratory Workforce

- Strengthen the laboratory workforce to support clinical and public health laboratory practice

Safe and Prepared Laboratories

- Enhance the safety and response capabilities of clinical and public health laboratories

Accessible and Usable Laboratory Data

- Increase access and use of laboratory data to support response, surveillance, and patient care

We Want to Hear From You!

Training and Workforce Development

CLCR calls are now LOCS calls!

Clinical Laboratory COVID-19 Response (CLCR) Calls are now Laboratory Outreach Communication System (LOCS) Calls. Find an archive of CLCR call audio files, transcripts, and slide presentations, [here](#).

CDC's Division of Laboratory Systems (DLS) convenes regular Laboratory Outreach Communication System (LOCS) calls with clinical laboratories and other audiences. The calls are an opportunity for CDC and other participants (such as federal partners and professional organizations) to provide updates and answer questions from the laboratory and testing community. These calls take place on the third Monday of each month at 3:00 PM Eastern time. DLS posts the audio, slides, and transcripts online after each call.

To submit questions for consideration, email DLInquiries@cdc.gov in advance or use the question and answer (Q&A) function in Zoom during the call. Because we anticipate a large number of participants on this call, and many questions, we may not be able to directly and immediately address every issue. However, we will note your questions and feedback and tailor the content of future calls accordingly.

On this page, you can find:

- LOCS Call information
- Transcripts
- Slides
- Audio Recordings

<https://www.cdc.gov/locs/calls>

How to Ask a Question

- **Using the Zoom Webinar System**
 - Click the **Q&A button** in the Zoom webinar system
 - Type your question in the **Q&A box** and submit it
 - **Please do not submit a question using the chat button**

- For media questions, please contact CDC Media Relations at media@cdc.gov
- If you are a patient, please direct any questions to your healthcare provider

Division of Laboratory Systems

Slide decks may contain presentation material from panelists who are not affiliated with CDC. Presentation content from external panelists may not necessarily reflect CDC's official position on the topic(s) covered.

Situational Update and Response to the Highly Pathogenic Avian Influenza A(H5N1) Outbreak in U.S. Dairy Cattle

Cattle Outbreak Update

- As of July 11, 2024, USDA has confirmed HPAI in dairy herds in **145** farms across 12 states:
 - CO (30), IA (13), ID (27), KS (4), MI (26), MN (7), NC (1), NM (8), OH (1), SD (5), TX (22), WY (1)**
- Other animal species reported on dairy premises:
 - 5 wild birds (2 TX farms)
 - 14 cats** (3 MI, 3 NM, 1 OH, 2 TX, 1 CO, 2 MN farms)
 - 2 racoons (1 NM, 1 MI)
 - 2 opossums (MI)

<https://www.aphis.usda.gov/livestock-poultry-disease/avian/avian-influenza/hpai-detections>

Monitoring of Exposed Persons

Monitoring Strategies

- Active outreach to states with positive cattle herds
- State public health labs perform monitoring of exposed individuals for symptoms and testing of symptomatic individuals
- Enhanced influenza surveillance
- Planned epidemiologic studies
- Since March 2024 >32,000 specimens have been tested at PHLs that would have detected A(H5) or other novel viruses.

Since Feb 2022 (bird exposure)

- CDC and state and local health departments actively monitor people exposed to infected birds, poultry or other animals for 10 days after exposure
 - At least 9,500 people monitored and
 - At least 350 people tested for novel influenza A

Current outbreak (cattle exposure)

- >1,390 people actively monitored
- Additional persons passively monitored
- States and CDC have tested >61 persons

The screenshot shows the CDC website interface. At the top, the CDC logo and tagline 'Centers for Disease Control and Prevention' are visible, along with a search bar. The main heading is 'Influenza (Flu)'. Below this, there's a breadcrumb trail 'Avian Flu > Information for Specific Groups'. A sidebar on the left contains a home icon and several expandable sections: 'Avian Flu', 'Current Situation', 'Bird Flu in Birds', 'Bird Flu in Pets and Other Animals', 'Bird Flu in People', 'Avian Influenza Type A Viruses', 'Prevention and Antivirals', 'Information for Specific Groups', and 'Information for People Exposed to'. The 'Information for Specific Groups' section is expanded, showing a link to the article 'Highly Pathogenic Avian Influenza A(H5N1) Virus in Animals: Interim Recommendations for Prevention, Monitoring, and Public Health Investigations'. The main content area features the article title, a 'Summary' section with a paragraph of text, and a 'Background' section. On the right side, there's a 'On This Page' section with a list of links: 'Summary', 'Background', 'Recommendations for the Public', 'Recommendations for Farmers', 'Recommendations for Clinicians', 'Recommendations for State Health Departments', and 'Recommendations for Surveillance and Testing'.

Health officials confirm human cases of avian flu in Colorado poultry workers

- Colorado Department of Public Health and Environment reporting a total of five human cases of avian influenza in workers responding to an avian influenza outbreak at a commercial egg layer operation on July 14th.
- CDC has confirmed four of the cases; one additional case is presumptive positive and pending confirmation at CDC.

A(H5N1) Human Case in Texas, 2024

Genetic sequencing of the viruses found in infected cattle and human sequence, indicate:

- B3.13 genotype:
 - PA, HA, NA and M gene segments from Eurasian wild bird lineages
 - PB2, PB1, NP and NS gene segments from American wild bird lineages.
- No known markers of resistance to approved antiviral drugs (PA, NA , M2)
- No impact of mutations to current CDC influenza diagnostic assays at U.S. and global public health laboratories' ability to detect H5N1 viruses
- Human virus sequenced (from the conjunctival sample and NP) had PB2 E627K mutation

Uyeki TM,... Davis CT. N Engl J Med. 2024 Jun 6;390(21):2028-2029.

[Technical Update: Summary Analysis of Genetic Sequences of Highly Pathogenic Avian Influenza A\(H5N1\) Viruses in Texas \(cdc.gov\)](#)

1st human case of A(H5N1) from Michigan

- No amino acid changes were identified in the HA gene sequence from the Michigan patient specimen compared to the HA sequence from the case in Texas
- The genome of the human virus from Michigan **did not** have the PB2 E627K change detected in the virus from the Texas case
 - Notable change (PB2 M631L) compared to the Texas case that is known to be associated with viral adaptation to mammalian hosts
 - Detected in 99% of dairy cow sequences but only sporadically in birds
- Genome of A/Michigan/90/2024 was closely related to sequences detected in infected dairy cows
- Virus isolation successful.
- No markers known to be associated with influenza antiviral resistance found
- Virus is closely related to two existing HPAI A(H5N1) candidate vaccine viruses that are already available to manufacturers, and which could be used to make vaccine if needed.

[Technical Update: Summary Analysis of the Genetic Sequence of a Highly Pathogenic Avian Influenza A\(H5N1\) Virus Identified in a Human in Michigan | Avian Influenza \(Flu\) \(cdc.gov\)](https://www.cdc.gov/flu/technicalupdate/summary-analysis-genetic-sequence-highly-pathogenic-avian-influenza-a-h5n1-identified-human-michigan)

2nd human case of A(H5N1) from Michigan

- **Partial HA and full-length NA of the viral RNA from the 2nd case from Michigan**
- **Virus isolation unsuccessful**
- No changes in the receptor binding domain that would impact infectivity or transmissibility between humans (i.e., no changes associated with receptor binding specificity; virus remains fully avian).
 - No HA changes identified in antigenic sites that would impact CVV cross-protection.
 - NA sequence confirms no changes associated with reduced antiviral susceptibility.

A(H5N1) case detected in Colorado

- **Genetic sequencing was not possible due to low viral load in sample**
- **Virus isolation unsuccessful**

Diagnostic testing

- **FDA granted enforcement discretion for the use of conjunctival swabs with the CDC Human Influenza Virus Real-Time RT-PCR Diagnostic Panel, Influenza A/H5 Subtyping Kit**
 - [05/31/2024: Lab Advisory: Enforcement Discretion Granted for the Use of Conjunctival Swabs with the CDC Human Influenza Virus Real-Time RT-PCR Diagnostic Panel, Influenza A/H5 Subtyping Kit](#)
 - Extended to November 1st
- **Completed recommendations/protocol for conjunctival sample collection methods for healthcare providers**
 - Produced a Desk Reference Graphic (i.e., Job-Aid) describing the procedure for collecting and transporting conjunctival specimens for H5N1 testing in a patient with conjunctivitis and suspected H5N1 infection.
 - [Conjunctival Swab Specimen Collection for Detection of Avian Influenza A\(H5\) Viruses \(cdc.gov\)](#)
 - Detailed protocol distributed to partners via CDC and APHL
- **Universal Transport Media being added to the Instructions for Use of CDC's A/H5**
 - Allow samples in this collection media to be tested using the CDC A/H5 assay

Thank you!

CDC Efforts to Expand Influenza Testing Capacity and Enhance Surveillance

Sean Courtney, PhD

CDC Division of Laboratory Systems

July 15, 2024
LOCS Call

Strategies to Improve Readiness and Testing Capacity

- Engagement with laboratories and industry partners to gauge interest in test development and validation studies
- CDC offers royalty free access to influenza A(H5) diagnostic test assay
 - Available since 2023
- CDC working with the Association of Public Health Laboratories (APHL) and the American Clinical Laboratory Association (ACLA) to disseminate information to laboratories

Royalty Free Licensing Agreements

- CDC Influenza A(H5) diagnostic assay design
- 15 agreements in progress with industry partners and commercial laboratories

Status	Number of Laboratories
Signed and executed agreements	8
Pending	3
In progress	4

Development of an Influenza A(H5) Test Utilizing CDC Assay Design

- Manufacturing companies can design, validate, submit, or pre-position for submission to FDA
- Engagement with companies to discuss assay designs
 - Molecular, multiplex, and rapid testing

Manufacturing Non-Virulent Control Material

- **Test development requires validation studies**
 - Control material needed for studies
- **Wild type virus and Candidate Vaccine Viruses (CVVs) used as control material require USDA permits to receive material and BSL-3+ (wt) or BSL-2+ (CVV) biosafety labs to handle infectious virus**
- **CDC developing alternative positive control material (BPL or gamma irradiated) inactivated influenza viruses to distribute**
 - Would **not** require USDA permit or enhanced biocontainment to handle

CDC Call to Industry

- **Primary Challenge: Influenza A(H5) subtyping tests only available at CDC and within state/local PHL networks**
 - Lack of access to testing in clinics/hospital networks may lead to delayed diagnosis of influenza A(H5)
 - Testing demand may exceed capacity/slow PH response if H5 epidemiology were to change in the future
- **Open call for innovative solutions to meet the CDC's diagnostic test development needs**
- **Competitive process for test developers to potentially obtain funding from CDC**
 - Develop, validate, manufacture test
 - Apply to FDA for regulatory approval and if approval is obtained to distribute test for influenza A(H5)
- **Concept papers under review**
 - Anticipate award contract(s) by the end of August 2024

Enhanced Summer Influenza Surveillance Strategy

- **Enhance surveillance in summer months**
 - Encourage ongoing influenza testing
 - Novel influenza A detection by subtyping Flu A specimens
 - Maintain flow of influenza positive specimens
 - Monitor data for any unexpected patterns
- **Updated guidance for submission criteria published on May 31, 2024**
- **Commercial laboratories submit Flu A and B positive samples to public health laboratories**

Flu A positive, subtype negative	Yes
Flu A positive, subtype A(H1)	Yes
Flu A positive, subtype A(H1)pdm09	No

Thank you!

Blood Culture Contamination: An Overview for Infection Control and Antibiotic Stewardship Programs Working with the Clinical Laboratory

[Blood Culture Contamination: An Overview for Infection Control and Antibiotic Stewardship Programs Working with the Clinical Laboratory \(cdc.gov\)](https://www.cdc.gov)

Blood Culture Contamination: An Overview for Infection Control and Antibiotic Stewardship Programs Working with the Clinical Laboratory

Purpose

Blood culture contamination can compromise quality of care and lead to unnecessary antibiotic exposure and prolonged length of hospitalization. Microbiology laboratories typically track blood culture contamination rates and can provide data to assist in reducing contamination rates. Infection control programs and microbiology laboratories might participate in designing and implementing interventions to decrease contamination rates, and antibiotic stewardship programs could also be engaged to optimize multidisciplinary quality improvement efforts to decrease blood culture contamination and improve the collection of blood culture specimens.

Background

Blood cultures are important diagnostic tools for identifying the pathogen(s) responsible for a patient's infection. This is especially true of patients with suspected sepsis or septic shock and for patients with suspected infective endocarditis^{1,2}. When indicated, blood cultures should be obtained prior to starting antimicrobial therapy^{3,4}. A conventional blood culture set consists of an aerobic and an anaerobic bottle. For adults, 20-30 mL of blood per venipuncture (depending on the instrument manufacturer) is recommended and may require >2 bottles depending on the system⁵. At least two blood culture sets should be obtained within a few hours of each other via peripheral venipuncture when obtaining blood cultures for a total volume of 40-60 mL of blood to optimize detection of pathogens⁶. The College of American Pathologists laboratory accreditation program states that clinical laboratories have a written policy and procedure for monitoring blood cultures from adults for adequate volume and provide feedback on the results to the collectors⁷. Moreover, the monitoring and reporting of blood culture contamination rates is a laboratory quality best practice⁸. Because blood is a normally sterile body site, positive blood cultures with a known pathogen have a generally overall high positive predictive value for infection. However, blood culture contamination is a significant problem. In the era of modern blood culturing techniques, virtually all blood culture contamination occurs during collection; the source of contaminants is usually the patient's skin or the hub or cannula of an indwelling catheter (i.e., when an existing catheter is used to obtain the specimen). Frequent causes include poor collection technique and insufficient skin disinfection. Typical organisms include coagulase-negative staphylococci, *Corynebacterium* spp., *Bacillus* spp. other than *Bacillus anthracis*, *Micrococcus* spp., and *Cutibacterium acnes* among others. Consequences include unnecessary antibiotic exposure with the potential for downstream unintended consequences (e.g., possible allergic reactions and *Clostridioides difficile* infection⁹). Other possible consequences include the unnecessary removal of intravenous catheters or other devices, an increased length of stay, and increased costs¹⁰. One study found that the average length of stay was 2 days longer in patients with contaminated blood cultures compared to patients with negative cultures¹¹. That same study found that direct and indirect hospital costs of a contaminated blood culture were \$12,824 compared to \$8,286 for a negative blood culture (savings of \$4,538 for preventing a contaminated blood culture¹²).

Example of a blood culture set consisting of an aerobic and an anaerobic bottle, with the latter after filling with an appropriate volume of blood.

Contaminated blood culture sets collected within 24 hours of skin disinfection. The contamination rate is 0.5%.

Using Blood Culture Contamination Rate for Quality Improvement

Many clinical laboratories routinely calculate and report the blood culture contamination rate as a quality metric at the beginning of the month to evaluate the previous month's rate. In addition to reporting rates regularly to infection prevention and antibiotic stewardship teams, specialized reporting of rates stratified by patient care locations and collection staff (e.g., nursing or phlebotomy teams), can be undertaken to better target improvement efforts.

Prevention/Actions¹³

An in-depth discussion of the ways to address the problem of the blood culture contamination can be found in the review article by Doern et al.¹⁴. A summary of the article follows.

Full article [here](#).

- 1. Diagnostic Stewardship**
Clinicians should strive to obtain blood cultures for the right patients, in the right settings, and at the right time. Blood cultures can be both underused and overused. An example of underuse would be not obtaining blood cultures prior to starting antibiotics for a patient with suspected sepsis. Without a blood culture collected before starting antibiotics, it can be more difficult to appropriately de-escalate antibiotic therapy given that the causative organism is more likely to remain unknown. Also, blood cultures can be underused if the appropriate volume is less than recommended (i.e., two to three 20 mL volumes of blood during initial evaluation of the patient for bacteremia) as this can decrease the sensitivity for pathogen detection. Cultures can also be overused; for example, obtaining repeat cultures in a patient with fever for whom an alternative diagnosis other than bloodstream infection is much more likely. In patients with a very low pretest probability of bloodstream infection, a positive culture is more likely to represent contamination than infection.
- 2. Proper Skin Antisepsis**
Improper skin antisepsis can lead to increases in blood culture contamination rates. It is recommended that the skin be disinfected with an alcohol containing disinfectant and allowed to dry prior to drawing blood cultures¹⁵.
- 3. Blood Culture Bottle Disinfection**
It is standard blood culture practice to disinfect the blood culture bottle tops prior to inoculation¹⁶.

Blood Culture Collection Site

venipuncture has consistently been shown to have lower rates of blood culture contamination than draws collected through central venous catheters¹⁷. Thus, peripheral blood cultures are preferred for drawn cultures except when the patient has a catheter-associated bloodstream infection suspected¹⁸. In these cases, both peripheral and catheter draws are indicated.

When a patient is recommended prior to venipuncture, it should be followed, a checkable. Such benchmark.

Key Terms and Education on Proper Phlebotomy

draws drawn by phlebotomy teams are more likely to be contaminated compared with draws collected by non-phlebotomy staff settings¹⁹.

IC and Feedback
IC programs have demonstrated that providing feedback to those performing blood cultures can decrease their contamination rates and decrease recontamination rates²⁰⁻²². Antibiotic stewardship programs can also consider tracking the impact of contamination rates on antimicrobial use.

Devices
Devices that are commercially available have shown promise in further reducing blood culture contamination rates. These devices are small amount of potentially contaminated blood and then collect blood for culture²³.

Considerations for Tracking Blood Culture Contamination Events

Antibiotic stewardship and infection prevention should meet with laboratory personnel to track and reporting of blood culture contamination events is being performed by the laboratory.

- Understand locations in the facility where blood culture contamination events occur most commonly, the type of staff who collect blood cultures, and how the collector is identified in the laboratory information system

CDC Division of Laboratory Systems
EXCELLENT LABORATORIES. OUTSTANDING HEALTH.

Preventing Adult Blood Culture Contamination: A Quality Tool for Clinical Laboratory Professionals

Protect Patients during the Diagnostic Process by Monitoring Adult Blood Culture Contamination (BCC) Rates

Laboratory analysis of blood cultures is vital to the accurate and timely diagnosis of bloodstream infections. However, the reliability of your testing depends on clinical compliance with collection procedures that limit the risk of inconclusive or incorrect results. False negative blood culture results due to inadequate volumes of blood can result in misdiagnosis, delay therapy, and put patients at heightened risk of morbidity and mortality from bacteremia. Likewise, the presence of commonly occurring bacteria or fungi on human skin (i.e., commensal organisms) can increase the risk of false positives, compromising care by leading to unnecessary antibiotic therapy and prolonged hospitalization.

In December 2022, a Centers for Medicare & Medicaid Services (CMS) consensus-based organization endorsed a CDC proposal for a new patient safety measure to address these concerns (see Quality Measures | CMS for more on this topic). CDC developed this quality measure to promote blood culture best practices and improve the laboratory diagnosis of bloodstream infection.

The Clinical Laboratory Improvement Amendments of 1988 (CLIA) state that laboratories must monitor, assess, and when indicated, correct problems identified in their preanalytic systems. Using the methods provided in this quality tool to calculate the BCC and single-set rates will help meet this standard and ensure optimal blood culture collection. In addition, this quality measure incorporates best practices on blood culture collection from the Clinical Laboratory Standards Institute (CLSI) and the Infectious Disease Society of America (IDSA). These best practices are already in place at many laboratories across the nation and have shown to improve the laboratory diagnosis of bacteremia, significantly reduce incidence of BCC, and limit unnecessary antibiotic therapy. CDC strongly encourages you to adopt these practices into your laboratory's standard operating procedures (SOPs), to integrate this measure into your quality management system, and to work with infection control and antibiotic stewardship programs to educate and train clinical staff on their use.

Follow CLIA Regulations

Laboratory Requirements, Code of Federal Regulations, Title 32 (2023): Chapter IV, Part 493 Subpart K – Quality System for Non-Waived Testing – § 493.1249 Standard: Preanalytic systems quality assessment.

The laboratory must establish and follow written policies and procedures for an ongoing mechanism to monitor, assess, and when indicated, correct problems identified in the preanalytic systems specified at §§ 493.1241 through 493.1242.

Collecting Adult Blood Culture Sets

A blood culture set from an adult patient should consist of 20–30 mL of blood collected through venipuncture. This may require more than two bottles, depending on the blood culture system and the institutional policy.

Collect Multiple Sets to Achieve the Optimal Volume

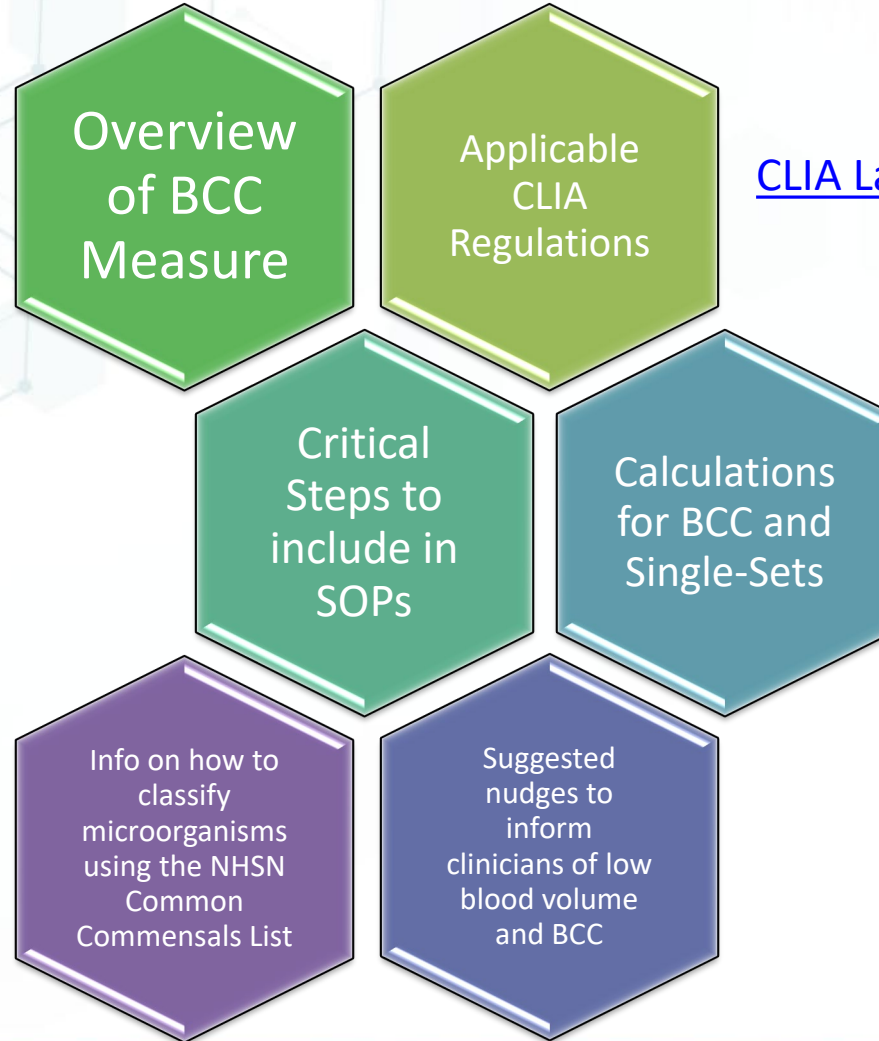

The volume of blood collected is critically important to the laboratory diagnosis of bloodstream infection, which generally requires two or more sets to achieve. In addition, two sets are required to determine whether the presence of a commensal organism can be classified as a possible contaminant.

To achieve an optimal volume, the blood culture collection standard of practice is to collect two to four blood culture sets from adult patients with a suspected blood stream infection in the evaluation of each septic episode (i.e., 24 hours). Your hospital or clinical setting should instruct healthcare staff to collect at least two blood culture sets (total volume of 40–60 mL) within a 24-hour period by peripheral venipuncture prior to antibiotic administration, if possible.

Take Home Messages

Those who collect blood cultures should be:

- Performing routine disinfection prior to collection to minimize the risk of contamination of the blood culture and the need to recollect additional blood cultures.
- Ensuring proper blood volume collection to avoid a need to recollect additional blood cultures.

Opportunities to improve inpatient blood culture (BCx) utilization

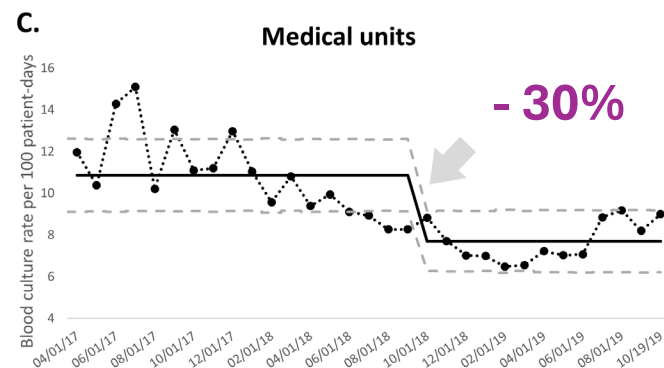

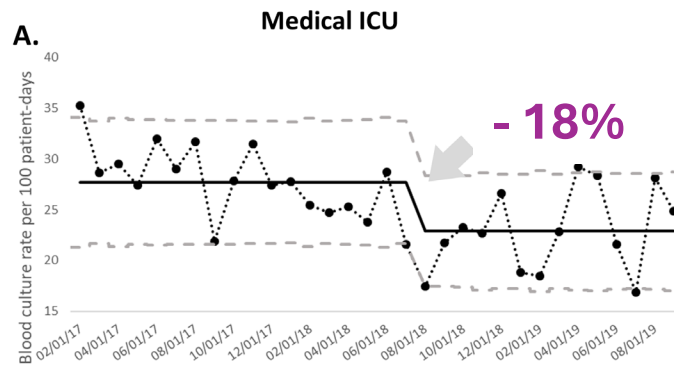

- >90% of BCx obtained from inpatients are negative  ng
- Based on an evidence-based algorithm (next slide), 30% of BCx in a medical ICU and 50% of BCx in medicine floors at a tertiary hospital in Baltimore were inappropriate
 - 60% of BCx in the ICU at a tertiary center in NYC
 - 40% of BCx in a Swiss hospital
 - 25% of BCx in a SICU at a tertiary hospital in North Carolina
- In 40-80% of BCx the appropriate volume is not collected
- ~20% of bacteremia cases were missed due to lack of anaerobic BCx, single sets, or inappropriate patient selection in a national study of BCx practices in Israel

Algorithm for bacterial blood cultures recommendations in non-neutropenic (adult) patients.

Implementation of a BCx algorithm to reduce unnecessary BCx in adult medicine units

- Education on BCx indications & collection best practices to ordering providers
- Implementation of the evidence-based BCx algorithm to guide BCx decisions (paper-based)
- Regular feedback regarding BCx utilization rates, and examples of inappropriate BCx

- **Reduction of single sets** in medicine floors
- **Increase in BCx positivity** in ICU
- No impact on Sep-1 measure, readmission, or mortality

Other hospitals have implemented the BCx algorithm (adult surgical ICUs at Duke¹, MICU and SICU at Baylor²) and have observed a 20-70% relative reduction in BCx utilization without safety concerns (readmission, length of stay, or 30-day mortality)

Opportunities to improve inpatient BCx utilization: Units with high BCx utilization

Hospital University of Pennsylvania (2015) –excluded BCx drawn in the ED for patients not admitted to the hospital-

- **General medicine 51.1%**
- **Oncology 25.9%**
- **Intensive care unit 19.0%**
- Surgery 18.4%
- Transplant 2.8%
- Emergency 1.8%

Delphi consensus recommendations for BCx in critically ill children

Consensus recommendations (R1-R19; see text) for blood culture use in critically ill children without signs of sepsis^{1,2}

“To Do” before blood culture decision:
 R1: Review the clinical data (e.g., vital signs, laboratory/imaging, urine output, recent cultures, antimicrobial therapy)
 R2: Examine the patient
 R3: Discuss the patient's clinical status with the bedside nurse

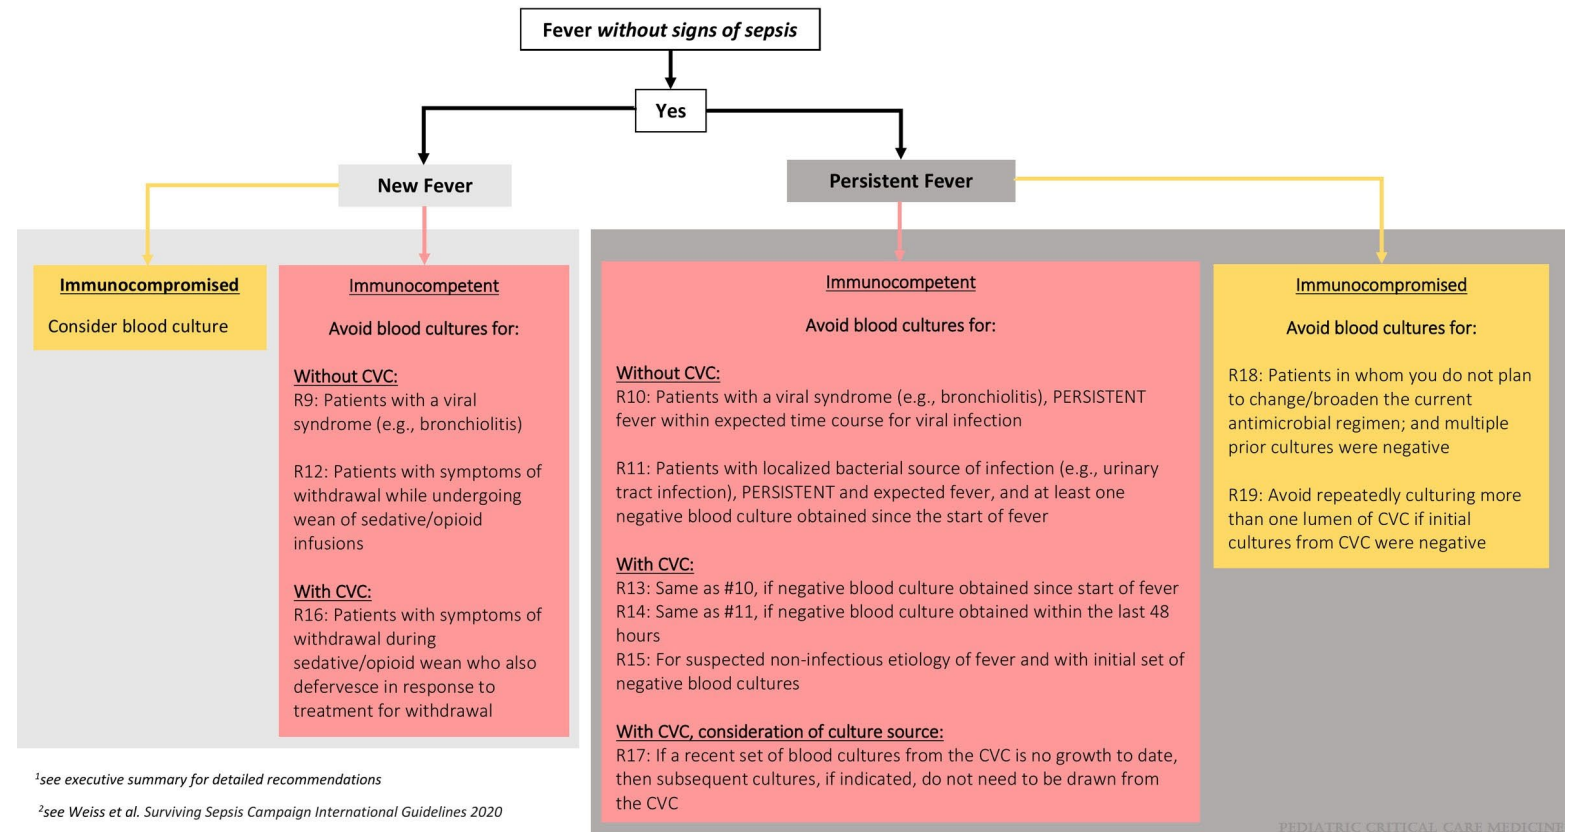

Do NOT:
 R7: Draw blood cultures from peripheral IVs
 R8: Obtain blood culture for NEW fever within 24 hours of surgery and with no signs of sepsis; WITH or WITHOUT a CVC in place

In ASYMPTOMATIC patients, avoid blood cultures:
 R4: For surveillance (e.g., daily screening blood cultures). In particular:
 R4a: on ECMO
 R4b: on CRRT
 R4c: in the immunocompromised WITH or WITHOUT CVC
 R5: In patients who have inadvertent CVC disconnection.
 R6: In patients who have a broken or cracked CVC

A LEARNING HEALTH COMMUNITY

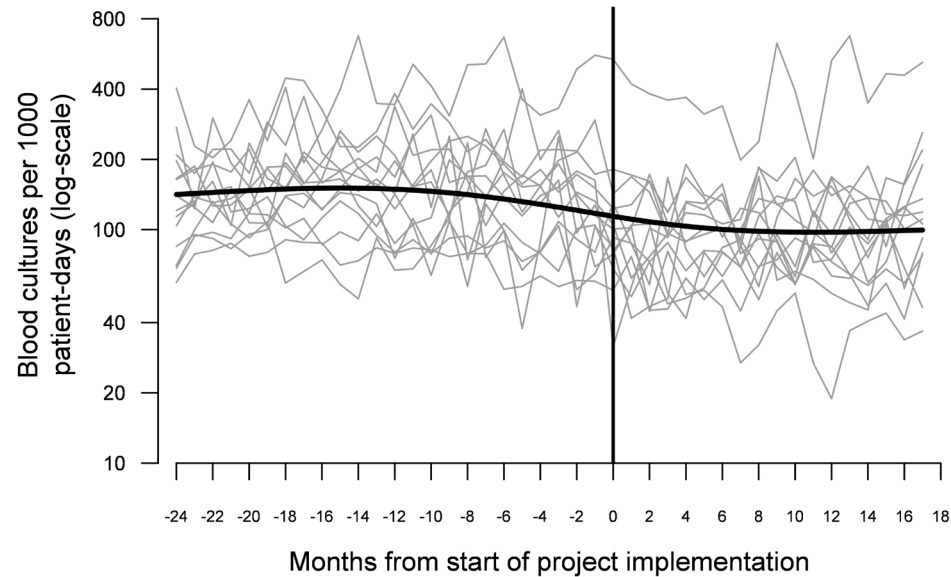

<http://HopkinsChildrens.org/brightstar>

¹see executive summary for detailed recommendations

²see Weiss et al. Surviving Sepsis Campaign International Guidelines 2020

Bright STAR results: blood cultures

33% relative reduction in BCx rate (95% CI: 26-39%)

- **36%** relative reduction in CLABSI rate (95% CI: 20-49%)
- **13%** relative reduction in broad-spectrum antibiotic use*
- No difference in mortality, PICU readmission, PICU length of stay before and after the intervention
- No difference in the number of sepsis, severe sepsis/septic shock cases before and after the intervention

*Days of broad-spectrum antibiotics for PICU days \geq 3

Summary

- BCx stewardship interventions have shown to safely reduce overall BCx use, while improving its utilization. This is a great opportunity to introduce BCx stewardship in your institutions and sustain it once the BCx bottle shortage subsides
- Microbiologists and Antibiotic stewardship/HEIC teams must work together to develop an appropriate BCx stewardship plan adapted to their current and anticipated BCx bottle supply
 - Implement guidance on appropriate indications with focus on reducing low yield BCx (include in local guidelines, educate ordering providers)
 - Implement EHR modifications
 - Implement prior-authorization

Summary: Low-yield BCx in adult inpatients

LOW-YIELD INITIAL BLOOD CULTURES

- Non-severe CAP
- Post-op fever within 48hs
- Isolated fever
- Isolated leukocytosis
- Persistent fever without clinical change and negative blood cultures in last 48-72 hours
- Persistent leukocytosis without clinical change and negative blood cultures in last 48-72 hours
- Non-severe CAP
- Non-severe cellulitis
- Post-operative fever within 48hs from surgery
- Lower UTI (cystitis, prostatitis)
- Surveillance blood cultures (e.g., before procedures, line placement, TPN initiation, etc.) in patients without suspicion for bacteremia

LOW-YIELD FOLLOW-UP BLOOD CULTURES

- Repeat blood cultures to document clearance of bacteremia caused by organisms other than *Staphylococcus aureus*, *Staphylococcus lugdunensis*, or *Candida* in patients without infective endocarditis/endovascular infection (e.g., cardiac device infection, septic thrombophlebitis) who showed clinical response and source control has been achieved
- Repeat blood cultures to rule out blood culture contamination in immunocompetent patients without prosthetic implants

SUGGESTED STRATEGIES TO CONSERVE BCx BOTTLES

- ✓ Meet with the Clinical Microbiology Laboratory to discuss current and expected BCx bottle supplies
- ✓ Identify clinical areas/units with highest BCx utilization
- ✓ Target high-use areas for education first
- ✓ Consider a stepwise approach to conserve BCx bottles based on anticipated supply reduction
- ✓ Prioritize reducing low-yield BCx first (expected reduction ~40% -70% depending on local practices)
- ✓ Meet with EHR to discuss implementation of electronic decision support tools to optimize BCx orders
 - Make most recent BCx results available upon clicking on a new BCx order
 - Hard-stops for repeat BCx
 - Include a link to the BCx algorithm or list low-yield indications to deter clinicians from ordering unnecessary BCx
 - Critically review order sets that contain blood cultures and remove blood cultures from order sets for conditions with low risk of bacteremia
